20 *Keywords:* Antiviral, chikungunya, CHIKV, Homology model, Molecular dynamics, Virtual screening

21

22 *Highlights:*

- 23 • *A homology model for the CHIKV nsP2 protease was constructed and validated.*
- 24 • *A new class of inhibitors of CHIKV replication was identified by virtual screening.*
- 25 • *SARs of the compound class were explored.*
- 26 • *Several analogues with low μ M activity in the cell-based assay were identified*

27

28

29 **ABSTRACT**

30 Chikungunya virus (CHIKV) is an Arbovirus that is transmitted to humans primarily by the
31 mosquito species *Aedes aegypti*. Infection with this pathogen is often associated with fever, rash and
32 arthralgia. Neither a vaccine nor an antiviral drug is available for the prevention or treatment of this
33 disease. Albeit considered a tropical pathogen, adaptation of the virus to the mosquito species *Aedes*
34 *albopictus*, which is also very common in temperate zones, has resulted in recent outbreaks in Europe
35 and the US. In the present study, we report on the discovery of a novel series of compounds that inhibit
36 CHIKV replication in the low μM range. In particular, we have initially performed a virtual screening
37 simulation of ~ 5 million compounds on the CHIKV nsP2, a viral protease, and then we have
38 investigated the Structure-Activity Relationships of the hit identified *in silico*. Overall, a series of 26
39 compounds, including the original hit, was evaluated in a virus-cell-based CPE reduction assay. The
40 study of such selective inhibitors will contribute to a better understanding of the CHIKV replication
41 cycle and represents also a first step towards the development of a clinical candidate drug for the
42 treatment of this disease.

43

44 **1. Introduction**

45 Chikungunya virus is an Arbovirus that belongs to the genus *Alphavirus*, family of the *Togaviridae*.
46 It is transmitted to humans primarily by the mosquito species *Aedes aegypti* (Sourisseau et al., 2007)
47 and the infection is associated with an acute pathology characterized by fever, rash and arthralgia
48 (Vanlandingham et al., 2005). In particular, the arthralgia symptoms, often severe and debilitating, may
49 persist for several months and become chronic in 10% of the infected individuals (Sissoko et al., 2009).

50 CHIKV infection was first described in Tanzania in 1952 (Ross, 1956) and small outbreaks have
51 been reported from time to time. However, since 2005, a re-emergence with a previously unknown
52 virulence was observed in large geographic areas around the Indian Ocean, extending from Africa,
53 India to South-East Asia (Arankalle et al., 2007), even reaching Europe (Hochedez et al., 2007) and the
54 US (CDC, 2007). The ability of the virus to adapt to a new vector, the mosquito species *Aedes*
55 *albopictus* (Tsetsarkin et al., 2009), may have significantly contributed to a rapid and worldwide spread
56 of this viral pathogen.

57 Clinically approved drugs such as chloroquine, alpha-interferon and ribavirin showed some
58 antiviral effect *in vitro* but did not prove to be effective against CHIKV infection *in vivo* (De

59 Lamballerie et al., 2008) (Khan et al., 2010). In the last few years, an increasing number of research
60 groups have focused their attention in identify novel anti-CHIKV compounds. As a result, different
61 natural products such as terpenoid compounds (Bourjot et al., 2012) and 5,7-dihydroxyflavones
62 (Pohjala et al., 2011), clinically approved drugs such as phenothiazinyl compounds (Pohjala et al.,
63 2011), arbidol (Delogu et al., 2011) and mycophenolic acid (Khan et al., 2011), along with the
64 synthetic IFN inducer Poly (I:C) (new-5) have shown to impair CHIKV replication in cell-based
65 systems (Li et al., 2012). Singh Kh et al. have also used a virtual screening approach to identify
66 possible new inhibitors of the CHIKV protease, but they did not evaluate experimentally the molecules
67 selected *in silico* (Singh Kh et al., 2012). Despite all these efforts, neither a selective antiviral drug nor
68 a vaccine has been approved for use in the clinical setting to date; care for CHIKV-infected patients is
69 still limited to supportive treatment aiming at alleviating the infection-induced symptoms (Solignat et
70 al., 2009).

71 CHIKV is an enveloped virus with an 11.8 kb single-stranded positive-sense RNA genome. It
72 contains two open reading frames and encodes four non-structural proteins (nsP1, nsP2, nsP3, nsP4),
73 three structural proteins (capsid, E1, E2) and two small polypeptides (E3, 6K) (Strauss and Strauss,
74 1994).

75 The four non-structural proteins possess enzymatic properties essential for virus replication and
76 therefore represent interesting targets for the identification of selective antiviral inhibitors. Among
77 them, the nsP2 protein plays a crucial role: its cysteine-protease activity is required for the proteolytic
78 cleavage of the non-structural polyprotein precursor into the four mature nsPs (Perri et al., 2000). Three
79 different cleavage sites, i.e. nsP1-2, nsP2-3, and nsP3-4, are the substrate for nsP2 proteolytic
80 processing with a remarkable preference for nsP3-4>nsP1-2>>nsP2-3 (Russo et al., 2010).

81 The present study aims to explore nsP2 as a target for the discovery and development of selective
82 inhibitors of CHIKV replication. In particular, we here report on the results obtained from a virtual
83 screening campaign of a library of commercially available compounds against an optimized homology
84 model of the CHIKV nsP2 protease. Furthermore, exploration of the structure-activity relationship and
85 initial chemical optimisation of the hit compound has led to the identification of novel compounds,
86 which are able to prevent virus-induced cell death at low μM concentrations.

87

88 **2. Materials and methods**

89 A detailed description of the Materials and Methods is available in the Supporting Information file.

90

91 **3. Results and Discussion**

92

93 *3.1 Homology model and validation*

94 At the time this project was initiated, the crystal structure of the CHIKV nsP2 was not yet resolved.
95 Therefore, we decided to use a comparative modelling approach to build a model of the CHIKV
96 protease. A homologous protein was identified by performing a similarity search between the sequence
97 of CHIKV nsP2 and the sequences of the 3D structures stored in the Protein Data Bank
98 (<http://www.rcsb.org/pdb>) through a PSI-BLAST search (Altschul et al., 1997). The Venezuelan equine
99 encephalitis virus (VEEV) nsP2 protease (PDB ID: 2HWK) (Russo et al., 2006) yielded the best
100 alignment score with a 40% sequence identity with the CHIKV sequence, thus representing a
101 promising template to start building the homology model from. The sequences were aligned by MOE
102 (Molecular Operating Environment, version 2009.10, Chemical Computing Group Inc.) with some
103 constraints as reported in detail in the Material and Methods section in the Supplemental Information
104 file. MOE was also used to construct the homology model which subsequently was validated in terms
105 of stereochemical quality through Ramachandran plots (Lovell et al., 2003) on the Cambridge
106 RAMPAGE server (<http://mordred.bioc.cam.ac.uk/~rapper/rampage.php>) and in terms of amino acids
107 environment using Verify 3D (Luthy et al., 1992) and Errat (Colovos and Yeates, 1993). The results
108 demonstrated that we constructed a fairly reliable model, both in terms of main-chain stereochemistry
109 as well as amino acid environment (Table 1). In the Ramachandran plot, 98.7% (favourable region:
110 94.7% plus allowed region: 4%) of the residues occupied the desired space.

111 Recent publication of the CHIKV nsP2 crystal structure (PDB ID: 3TRK) has retrospectively
112 confirmed the reliability of our homology model: the backbone C α superposition between the crystal
113 structure and the homology model has a RMSD value of 1.78 Å (Fig. S1). Moreover, the RMSD value
114 for the superposition of the binding site (19 residues within 4.5Å of the natural ligand) is significantly
115 lower (0.82 Å), confirming the accuracy of the model in reproducing the active site characteristics. The
116 overall structural overlap between the model and the template became more evident when comparing
117 the architecture of the active site with the bound natural substrate (Fig. 2).

118

119 3.2 *Virtual screening*

120 The active site of the CHIKV nsP2 model was used to perform a structure-based virtual screening
121 study with commercially available compounds. The starting point was a database of ~5 million
122 structures, which was filtered using the pharmacophore model based on the protease binding site (Fig.
123 1). This process resulted in an enriched library of 12121 structures that possessed the required
124 structural features. Molecular docking of these compounds was then performed using two different
125 software packages: PLANTS (version 1.1) (Korb et al., 2009) and LeadIT-FlexX(version 1.2) (Rarey et
126 al., 1996).

127 The docking results were subsequently re-scored using a multi-step consensus score. The first step
128 encompassed a “rank sum” strategy that is widely used in docking experiments (Wang and Wang,
129 2001). The idea of the “rank sum” strategy is to rank all molecules according to each individual scoring
130 function and to use the sum of the rank positions of the poses as a score. This resulted in two different
131 hit lists, one based on the LeadIT-FlexX binding mode prediction, the other based on the PLANTS
132 software. The second step comprised a voting strategy. The idea of the “vote rank” is that each scoring
133 function votes for a pose to be a hit if the pose obtained a score in the top 25% of the score value range
134 for all poses of a molecule. The number of votes for each pose finally serves as the consensus score to
135 prioritize the compound structures.

136 A final selection of 15 derivatives was made by visual inspection; 9 of these compounds could be
137 purchased and their potential antiviral activity on *in vitro* chikungunya virus replication was assessed.
138 The molecules were subsequently submitted for evaluation of selective antiviral activity in a virus-cell-
139 based assay for chikungunya virus.

140

141 3.3 *Lead compound identification and biological validation.*

142 Of these 9 hits obtained from the virtual screening, compound **1** selectively inhibited CHIKV-
143 induced with an EC₅₀ value of 5.0 μM in the cytopathic effect (CPE) reduction assay (Table 3, Fig.
144 3A). The proposed binding configuration of **1** in the active site of CHIKV nsP2 is shown in Fig. 4. The
145 compound is predicted to fit the central portion of the nsP2 protease active site, with its hydrazone
146 group placed in the region defined by the catalytic dyad, Cys579 and His649, and also in close
147 proximity of Trp650. The cyclopropane moiety is positioned in the space previously occupied by the
148 second glycine residue of the nsP3-4 junction peptide. The most relevant interactions observed for **1**

149 are a hydrophobic contact between the 3,4-diethoxyphenyl ring and the lateral chain of Trp650, two
150 hydrogen-bond connections between the hydrazone function and the backbone amido groups of Tyr613
151 and Asn648 and another hydrophobic interaction between the *t*-butylic group of **1** and His649 (Fig 4,
152 Fig. S2). It is interesting to note that docking **1** in the crystal structure of the CHKV nsP2 produced a
153 virtually identical binding pose (Fig. S3).

154 Biological validation of the selective antiviral effect of Compound **1** on the replication of
155 chikungunya virus was obtained by performing a virus yield assay in Vero cells. This assay allows
156 quantification of the dose-response effect of the compound at two levels: (1) at the level of viral RNA
157 production by quantification of the amount of viral RNA that is released in the supernatant
158 (encapsidated in progeny virions; by RT-qPCR) and (2) at the level of infectious virus particle
159 production by quantification of the amount of infectious progeny virions that are released by virus-
160 infected compound-treated cells (by titration for infectious virus content). EC₅₀ values of respectively
161 4.3 and 4.9 μM were derived from the dose-response curves obtained by both respective methods (Fig.
162 3B), of which is very similar to the EC₅₀ obtained from the CPE reduction assay (Fig. 3A). Of
163 importance, however, is to note that inhibition of virus replication is observed at concentrations that do
164 not cause an adverse effect on the host cells (Fig. 3A), thus validating the compound as a selective
165 inhibitor of virus replication.

166 Chloroquine was included as reference compound. It is one of the few compounds that have been
167 reported in the literature to significantly inhibit CHIKV replication. Chloroquine a-specifically inhibits
168 CHIKV replication by interfering with the protonation of endocytotic vesicles, a step that is essential to
169 allow the virus to release its RNA into the cell cytoplasm. Chloroquine was found to be about 2-fold
170 less potent in the virus-cell-based CPE reduction assay as compared to compound **1** (10 ± 1.4 μM vs 5
171 ± 0.2 μM). The antiviral effect of both compounds in the virus yield assay was quite similar and in
172 agreement with the earlier reported *in vitro* antiviral activity of chloroquine (Khan et al., 2010).

173

174 3.4 Chemical validation and initial Structure-Activity Relationships analysis

175 To explore the potential of this molecular scaffold as selective inhibitors of CHIKV replication, a
176 series of 23 structural analogues of compound **1** (Table 2, compounds **2-24**) was acquired from the
177 SPECS library (<http://www.specs.net>). These compounds were identified by performing a chemical
178 similarity search in the SPECS library, using compound **1** as the query. This initial series of

179 compounds was evaluated for selective antiviral activity in the CHIKV virus-cell-based assay (Table
180 3). Structurally, the compounds could be divided in two groups. Compounds **2-15** present two aromatic
181 moieties and a cyclopropane ring, as observed in **1**. The second group (compounds **16-24**) is more
182 diverse and, although these analogues still include the common carbonyl hydrazone linker, they do not
183 contain a cyclopropane moiety in the alpha position to the carbonyl carbon. In most of the structures,
184 the central core is asymmetrically substituted with two hydrophobic groups, with most of them carrying
185 different substituents in diverse positions.

186 According to the activity data obtained for this initial series (Table 3), the cyclopropyl moiety
187 seems to be important for the anti-CHIKV effect as compounds **16-24** did not show significant
188 biological activity. A SAR analysis performed on **1-15** did not allow drawing definite conclusions, but
189 it seems that the presence of an aliphatic group in *para* position of the benzylidene group is beneficial
190 for antiviral activity (e.g. compounds **8** and **13**). It should be noted that the purchased compounds were
191 evaluated by ¹H-NMR for purity. Furthermore, for chemical validation purposes, compound **1**, **6** and **8**
192 were synthesised in our lab (Scheme 1A) and the spectroscopic data confirmed that the molecules were
193 identical to the purchased compounds.

194

195

196 3.5 Design and synthesis of new derivatives

197 The biological data provided us with a starting point for further optimisation of these compounds.
198 The next objective was to identify a suitable replacement of the cyclopropane ring, as the two chiral
199 centres on this group could present a challenge in the preparation and purification of new analogues.
200 Furthermore, replacement of the hydrazone group would be beneficial to overcome possible chemical
201 instability issues (susceptible to hydrolysis). Compound **25** and **26** were designed to explore such
202 modifications. In both structures, the cyclopropyl group was replaced with a *trans*-ethenyl function,
203 which allows maintaining length and geometry of the original linker while avoiding the presence of any
204 chiral centre in the molecule. Compound **25** differs from **1** only for this moiety, while in compound **26**,
205 a first attempt was made to also replace the hydrazone moiety with an amide linker. Both compounds
206 were able to dock in the nsP2 binding site in a similar binding pose as **1** (Fig S4). Biological evaluation
207 of **25** and **26** provided a clear outcome: the loss of activity of the latter indicates that further structural
208 optimisation studies are required to identify a suitable alternative for the hydrazone group; however, **25**

209 showed a slightly improved antiviral activity profile compared to **1** (Table 3), indicating that the
210 proposed replacement of the cyclopropane is acceptable (Fig. 3).

211

212 **4. Conclusions**

213 The work presented in this study underlines the usefulness of using a molecular modelling
214 methodology that includes different *in silico* techniques in combination with a more classical medicinal
215 chemistry approach, in the identification for novel and selective antiviral compounds. In this case, by
216 using homology modelling and virtual screening, we identified a novel class of inhibitors of *in vitro*
217 chikungunya virus replication. Starting from the original *in silico* hit (**1**), we were able to further
218 expand the series of active compounds by using a more classic structure-activity relationships
219 approach. In particular, compound **25** has a very promising activity profile and a simplified molecular
220 structure compared to **1**, which will allow a more rapid and efficient optimization of this class of
221 compounds by using a more accessible synthetic route. It is important to underline that despite the
222 results of the molecular modeling studies, further experimental studies (currently ongoing) are required
223 to prove that these compounds are indeed nsP2 inhibitors. However, notwithstanding the mode of
224 action of these novel inhibitors, the promising results reported here could represent an initial step
225 towards the discovery of a clinical candidate for the treatment of CHKV infections.

22	NA	NA	>318	-
23	NA	NA	>291	-
24	NA	NA	>446	-
25	3.2 ± 1.8	11 ± 4	101 ± 50	32
26	NA	NA	54	-

^aThe selectivity index SI is calculated as the ratio of CC₅₀/EC₅₀.

Data are mean values ±SD for at least 3 independent experiments

NA = no activity could be observed

- = value could not be calculated

Fig. 1. Pharmacophore model used to filter the small molecule databases for the virtual screening studies on the model active site. The model consists of a hydrophobic/aromatic interaction with the residues Asn577, Cys579 and Ala612 (yellow - F1), one hydrogen bond acceptor point to Trp650 (cyan), an aromatic interaction with residues Tyr613, Met804 and Met808 (yellow - F3) and one hydrogen bond donor to Tyr645 (pink). Exclusion volumes are not shown for clarity.

Fig. 2. Superposition between the crystal structure (in pink) and the model (in green) active sites and their relative position in reference to the nsP3-4 junction peptide (in white) optimised within the model structure.

Fig. 3. Chloroquine (●), Compound 1 (○) and Compound 25 (●) inhibit CHIKV replication *in vitro*. (A) Dose-response effect on uninfected host cells as measured by cell survival/viability; (B) Dose-response effect on virus replication as measured by cell survival (inhibition of virus-induced cytopathic effects); (C) Dose-response effect on virus replication as measured by inhibition of RNA replication (real-time quantitative RT-PCR readout); (D) Dose-response effect on virus replication as measured by inhibition of infectious progeny virion production (quantified by titration for infectious virus content). Results shown are the average + SD of at least 4 independent experiments.

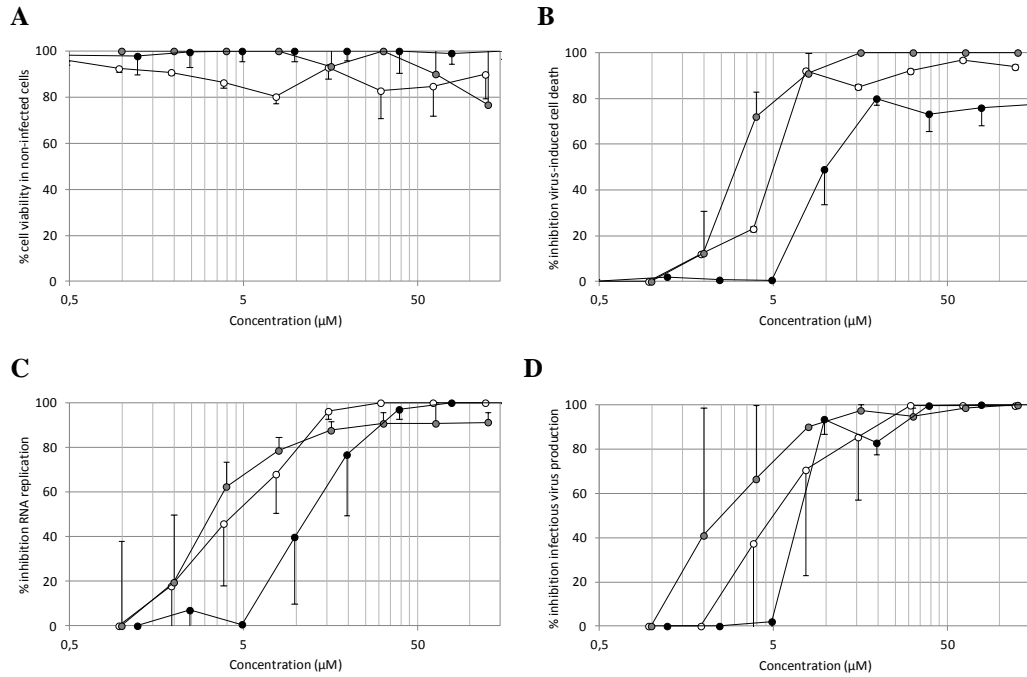

Fig. 4. Docking pose of **1** in the model of the CHKV nsP2 binding pocket.

Scheme 1. Synthesis of compounds 1, 6, 8, 25 and 26.^a

^aReagents and reaction conditions: (a) ethyldiazoacetate, tert-butylstyrene, 125 °C, 4 h, nitrogen atmosphere, R.T. overnight, yield 60%; (b) hydrazine monohydrate (60%), methanol, reflux, 12 h, yield 80%; (c) EtOH, reflux, 16 h, yield 20-90%; (d) malonic acid, catalytic piperidine, pyridine, R.T., 3 h, yield 95%; (e) i. oxalyl chloride, diethyl ether, R.T., 3 h, nitrogen atmosphere; ii. hydrazine monohydrate (60%), R.T., 2 h, yield 40%; (f) 3,4-diethoxybenzaldehyde, EtOH, reflux, 16 h, yield 25%; (g) 3,4-dimethoxybenzylamine, TBTU, diisopropylethylamine, anhydrous THF, R.T., 4 h, yield 96%.
