The authors propose a novel time-domain extension of the well-known frequency-domain surface-impedance method in computational magnetodynamics. Herein the 1-D eddy-current problem in a massive conducting region (semi-infinite slab) is considered via a number of exponentially decreasing trigonometric basis functions that cover the relevant skin-depth (or frequency) range of the application at hand. The method is elaborated for the 3-D magnetic-vector-potential formulation and is applied to a simple 2-D test case. Results are shown to converge well to those obtained with an accurate brute-force FE model.

Index Terms—Finite-element methods, surface-impedance boundary conditions, magnetodynamics, time-domain analysis

I. INTRODUCTION

SURFACE-IMPEDANCE boundary conditions (SIBCs) are widely applied in frequency-domain eddy-current problems for considering massive conducting regions. The approach is based on the relation between the tangential components of the electric and the magnetic field at the surface of the conducting region and allows to discretize the surface of the region only. A necessary condition is that at the considered frequency the skin depth is sufficiently small compared to the depth or curvature of the conducting region. Several refinements have been presented in literature, which mostly concern the curvature of the surface [1], but also the saturation of the material [2].

The few time-domain extensions proposed to date are mostly based on the fast Fourier transform [3], on the explicit and separate resolution of a large number of 1-D FE models (with classical nodal basis functions) parallel to the main 3-D FE model [4], or on the convolution product [1]. The time-domain approach presented in this paper relies on the spatial discretisation of the 1-D eddy-current problem by means of dedicated basis functions which are derived from the analytical frequency-domain solution. The method is first briefly elaborated in sections II and III and then validated by means of a simple 2-D test case in section IV.

II. 1-D EDDY CURRENT PROBLEM IN SEMI-INFINITE SLAB

A. Magnetic-vector-potential formulation

In this paper we are concerned with low-frequency eddy-current problems. The following Maxwell equations and constitutive laws are taken into account:

$$\begin{aligned} \text{div } \underline{b} &= 0, & \text{curl } \underline{h} &= \underline{j}, & \text{curl } \underline{e} &= -\partial_t \underline{b}, & (1 \text{ a-c}) \\ \underline{j} &= \sigma \underline{e}, & \underline{b} &= \mu \underline{h}, & & & (2 \text{ a b}) \end{aligned}$$

where the vector fields $\underline{b}$, $\underline{h}$, $\underline{j}$ and $\underline{e}$ are the flux density (or induction), the magnetic field, the current density and the electric field respectively; σ , μ and $\nu = 1/\mu$ are the conductivity, the permeability and the reluctivity respectively. We consider a bounded domain Ω in the 3-D Euclidean space

that comprises linear and homogenous media only, i.e. σ , μ and ν are constant scalars for each medium present in Ω .

We introduce the magnetic vector potential $\underline{a}$ in order to satisfy (1a,c) strongly:

$$\underline{b} = \text{curl } \underline{a}, \quad \underline{e} = -\partial_t \underline{a}. \quad (3)$$

The remaining equations in (1-2) lead to the following partial differential equation:

$$\text{curl}(\nu \text{curl } \underline{a}) = \underline{j}_s - \sigma \partial_t \underline{a}, \quad (4)$$

where $\underline{j}_s$ is the prescribed source current density in a subdomain Ω_s of Ω ; in another conducting subdomain Ω_c the current density is induced and given by $-\sigma \partial_t \underline{a}$.

B. Analytical solution for 1-D eddy-current model

We consider now the 1-D eddy-current problem in a semi-infinite slab ($0 \leq x \leq \infty$), with $\underline{b}(x,t)$ and $\underline{h}(x,t)$ parallel to the z -axis, and $\underline{j}(x,t)$ and $\underline{e}(x,t)$ parallel to the y -axis. The source current density $\underline{j}_s$ is zero. With the y -component of the vector potential $\underline{a}(x,t)$ denoted by $a(x,t)$, (4) becomes

$$\partial_x^2 a = \sigma \mu \partial_t a \quad \text{with} \quad a(x = \infty, t) = 0, \quad (5)$$

where the boundary condition at infinity ($x = \infty$) ensures the uniqueness of $a(x,t)$.

The sinusoidal steady-state solution at frequency f (pulsation $\omega = 2\pi f$), with boundary condition $a(x = 0, t) = \hat{a} \cos(\omega t + \phi)$, reads

$$a(x,t) = \hat{a} e^{-x/\delta} \cos(x/\delta - \omega t - \phi), \quad (6)$$

$$\begin{aligned} &= \hat{a} \cos(\omega t + \phi) e^{-x/\delta} \cos(x/\delta) \\ &\quad + \hat{a} \sin(\omega t + \phi) e^{-x/\delta} \sin(x/\delta), \end{aligned} \quad (7)$$

where $\delta = \sqrt{2/(\mu\sigma\omega)}$ is the skin depth and ϕ an arbitrary phase angle.

Using the complex notation (symbols in bold, imaginary unit $\sqrt{-1}$ denoted by $\mathbf{i}$), we rewrite (6) as follows

$$a(x,t) = \Re(\hat{a} e^{-\frac{1+\mathbf{i}}{\delta}x} e^{\mathbf{i}(\omega t + \phi)}), \quad (8)$$

$$\Rightarrow \mathbf{a}(x) = \hat{a} e^{\mathbf{i}\phi} e^{-\frac{1+\mathbf{i}}{\delta}x}, \quad (9)$$

which further leads to a relation between the induction $\underline{b} =$

This work was partly supported by the Belgian Science Policy (IAP P6/21).

curl $\underline{a}$ and the electric field $\underline{e} = -\partial_t \underline{a}$ at the surface $x = 0$:

$$\partial_x \underline{a} \Big|_{x=0} = -\frac{1+i}{\delta} \underline{a}(x=0). \quad (10)$$

It is this equation that is at the heart of the classical frequency-domain SIBC approach.

C. Low-order time-domain model of semi-infinite slab

We now develop a low-order model of the 1-D eddy-current problem by adopting n skin depths δ_k , $1 \leq k \leq n$, in agreement with the frequency spectrum of the magnetic fields in the problem at hand (see e.g. the application example hereafter and the one in section III). Based on the analytical solution (7), we define the following $2n$ basis functions:

$$\alpha_{c1}(x) = e^{-x/\delta_1} \cos(x/\delta_1), \quad (11)$$

$$\alpha_{ck}(x) = e^{-x/\delta_k} \cos(x/\delta_k) - \alpha_{c1}(x), \quad 2 \leq k \leq n, \quad (12)$$

$$\alpha_{sk}(x) = e^{-x/\delta_k} \sin(x/\delta_k), \quad 1 \leq k \leq n. \quad (13)$$

Note that all basis functions vanish at the boundary $x = 0$ except the first one, for which we have $\alpha_{c1}(x=0) = 1$.

The associated expansion of $a(x, t)$ is written in matrix form as follows:

$$a(x, t) = [A(t)]^T [\alpha(x)], \quad (14)$$

with the $2n \times 1$ column matrices $[A(t)]$ and $[\alpha(x)]$ given by

$$[A(t)] = [a_{c1}(t) \dots a_{cn}(t) a_{s1}(t) \dots a_{sn}(t)]^T, \quad (15)$$

$$[\alpha(x)] = [\alpha_{c1}(x) \dots \alpha_{cn}(x) \alpha_{s1}(x) \dots \alpha_{sn}(x)]^T. \quad (16)$$

The classical variational FE approach leads to a system of $2n$ first-order differential equations in terms of the elements of $[A(t)]$:

$$[S][A] + [M] \partial_t [A] = 0, \quad (17)$$

where the elements of $[S]$ and of $[M]$ are given by

$$S_{ij} = \nu \int_0^\infty \partial_x \alpha_i(x) \partial_x \alpha_j(x) dx, \quad (18)$$

$$M_{ij} = \sigma \int_0^\infty \alpha_i(x) \alpha_j(x) dx. \quad (19)$$

An analytical expression of these elements can be straightforwardly derived given the following three equations:

$$\begin{aligned} & \int_0^\infty e^{-x/\delta_k} e^{-x/\delta_l} \begin{bmatrix} \cos(x/\delta_k) \cos(x/\delta_l) \\ \cos(x/\delta_k) \sin(x/\delta_l) \\ \sin(x/\delta_k) \sin(x/\delta_l) \end{bmatrix} dx \\ &= \frac{\delta_k \delta_l}{2(\delta_k + \delta_l)(\delta_k^2 + \delta_l^2)} \begin{bmatrix} \delta_k^2 + \delta_l^2 + \delta_k \delta_l \\ \delta_k^2 \\ \delta_k \delta_l \end{bmatrix}. \end{aligned} \quad (20)$$

The associated positive-definite quadratic forms are the instantaneous magnetic energy density $w(t)$ and the instantaneous eddy-current loss density $p(t)$:

$$w = [A]^T [S] [A] \quad \text{and} \quad p = \partial_t [A]^T [M] \partial_t [A]. \quad (21)$$

Further note that $[S]$ and $[M]$ can be normalized considering e.g. the first skin depth δ_1 and associated pulsation $\omega_1 = 2\nu/(\sigma\delta_1^2)$:

$$[S^*] = \frac{\delta_1}{\nu} [S] \quad \text{and} \quad [M^*] = \frac{1}{\delta_1 \sigma} [M], \quad (22)$$

where the dimensionless matrices $[S^*]$ and $[M^*]$ depend only

on the $n-1$ skin-depth ratios $\delta_2/\delta_1 = \sqrt{\omega_1/\omega_2}$ to $\delta_n/\delta_1 = \sqrt{\omega_1/\omega_n}$. Equation (17) then becomes

$$[S^*][A] + \frac{2}{\omega_1} [M^*] \partial_t [A] = 0. \quad (23)$$

D. Validation and application example of low-order model

We now modify (17) in order to have the surface value of the magnetic vector potential, i.e. $a_{x=0}(t) = a_{c1}(t)$, as source for the eddy-current problem. By removing $a_{c1}(t)$ from $[A(t)]$ we obtain the column matrix of $2n-1$ effective degrees of freedom, denoted by $[A'(t)]$, and the associated system of $2n-1$ differential equations reads

$$[S'] [A'] + [M'] \partial_t [A'] = -([s] a_{x=0} + [m] \partial_t a_{x=0}), \quad (24)$$

where the square matrices $[S']$ and $[M']$ and the column matrices $[s]$ and $[m]$ are straightforwardly obtained from $[S]$ and $[M]$.

Considering the sinusoidal regime at pulsation ω , (24) is transformed into

$$([S'] + i\omega [M']) [A'] = -([s] + i\omega [m]) a_{x=0}, \quad (25)$$

and the derivative $\partial_x a(x)$ at the surface $x = 0$ can be written as follows:

$$\partial_x a(x) \Big|_{x=0} = -\frac{1}{\delta_1} a_{x=0} + [v]^T [A'], \quad (26)$$

where the first $n-1$ elements of the column matrix $[v]$ are given by $1/\lambda_1 - 1/\lambda_2$ to $1/\lambda_1 - 1/\lambda_n$, and the last n elements by $1/\lambda_1$ to $1/\lambda_n$.

We thus find the approximation of (10) given the n pairs of basis functions of the low-order model:

$$\partial_x a \Big|_{x=0} = -\frac{\mathbf{Z}_n}{\delta} a(x=0), \quad (27)$$

where $\mathbf{Z}_n$ is a function of δ/δ_1 (or ω/ω_1) and of the $n-1$ skin-depth ratios δ_2/δ_1 to δ_n/δ_1 :

$$\mathbf{Z}_n = \frac{\delta}{\delta_1} + \delta [v]^T \left([S'] + i\omega [M'] \right)^{-1} ([s] + i\omega [m]). \quad (28)$$

When the skin depth δ is equal to one of the n preset skin depths, the low-order model gives the exact result, i.e. $\mathbf{Z}_n(\delta) = 1 + i$, as the analytical solution can be restituted by two of the $2n$ basis functions. For intermediate values of δ and values outside the range covered by the n preset skin depths, some error is inevitable.

We verify this considering n subsequently equal to 1, 2 and 3, and with $\omega_2/\omega_1 = 3$ and $\omega_3/\omega_1 = 5$. Figure 1 shows the real and imaginary part of $\mathbf{Z}_1$, $\mathbf{Z}_2$ and $\mathbf{Z}_3$ with δ/δ_1 ranging from 1/4 to 2 (or ω/ω_1 ranging from 1/4 to 16). One clearly observes the convergence of $\mathbf{Z}_n$ towards the exact solution (real and imaginary part both equal to 1) with increasing n .

III. FE IMPLEMENTATION

We consider a 3-D domain Ω that comprises a source domain Ω_s (with given $\underline{j}_s$) and a conducting domain Ω_c with induced current ($\underline{j} = -\sigma \partial_t \underline{a}$). The SIBC method will be applied to a massive subdomain Ω_m of Ω_c . In the classical (frequency-domain) approach the weak form of the Ampère

Fig. 1. Real and imaginary part of Z_1 , Z_2 and Z_3 as a function of $\sqrt{f/f_1} = \sqrt{\omega/\omega_1} = \sqrt{\lambda_1/\lambda}$ with $\omega_2/\omega_1 = 3$ and $\omega_3/\omega_1 = 5$

law (4) is first written as follows:

$$\left(\nu \operatorname{curl} \underline{a}, \operatorname{curl} \underline{a}' \right)_{\Omega/\Omega_m} + \left(\sigma \partial_t \underline{a}, \underline{a}' \right)_{\Omega_c/\Omega_m} + \left\langle \underline{n} \times \underline{h}, \underline{a}' \right\rangle_{\partial\Omega_m} = \left(\underline{j}_s, \underline{a}' \right)_{\Omega_s}, \quad (29)$$

where $(\cdot, \cdot)_{\Omega}$ and $\langle \cdot, \cdot \rangle_{\partial\Omega_m}$ are the integrals on the domain Ω and on the boundary $\partial\Omega_m$, respectively, of the product of the two arguments; $\underline{n}$ is the outward normal on $\partial\Omega_m$. The integral of the tangential magnetic field $\underline{n} \times \underline{h}$ on $\partial\Omega_m$ is then expressed in terms of the tangential electric field $\underline{n} \times \underline{e} = -\underline{n} \times \partial_t \underline{a}$ thanks to (10). The domain Ω/Ω_m , its boundary and the weak form (29) can be discretized by Whitney edge elements, leading to a system of linear first-order differential equations in terms of the degrees of freedom of $\underline{a}$ (circulation of $\underline{a}$ on the edges of the FE mesh) [5].

In the approach proposed in this paper the surface-integral term in (29) is not exploited as such, but the two volume integrals considered for Ω_m will be reduced to surface integrals. Hereto we consider a local coordinate system xyz on $\partial\Omega_m$, with the x -axis parallel to $\underline{n}$ and inward Ω_m . Further ignoring the finite depth of Ω_m and the nonzero curvature of $\partial\Omega_m$, we write the magnetic vector potential in the transformed domain Ω_m as follows: $\underline{a} = \underline{a}_t(y, z) p(x, t)$, where $\underline{a}_t$ is tangential to $\partial\Omega_m$ and where $p(x, t)$ is differentiable with respect to x ($0 \leq x < \infty$). The two volume integrals on Ω_m are then worked out accordingly:

$$\left(\nu \operatorname{curl} \underline{a}, \operatorname{curl} \underline{a}' \right)_{\Omega_m} = \left\langle \operatorname{curl} \underline{a}_t, \operatorname{curl} \underline{a}'_t \right\rangle_{\partial\Omega_m} \cdot \nu \int_0^\infty \partial_x p \partial_x p' dx, \quad (30)$$

$$\left(\sigma \partial_t \underline{a}, \underline{a}' \right)_{\Omega_m} = \left\langle \partial_t \underline{a}_t, \underline{a}'_t \right\rangle_{\partial\Omega_m} \cdot \sigma \int_0^\infty p p' dx. \quad (31)$$

Considering the n pairs of basis functions $\alpha_{ck}(x)$ and $\alpha_{sk}(x)$ for the space discretisation of $p(t)$ and test functions $p'(t)$, the integration along the x -axis in (30,31) produces the elements of the matrices $[S]$ and $[T]$.

The number of spatial degrees of freedom of $\underline{a}$ on $\partial\Omega_m$ (and in Ω_m) is thus equal to the number of edges on $\partial\Omega_m$ times $2n$. In the 2-D case, adopting a one-component vector potential

and nodal basis functions, the number of spatial degrees of freedom is equal to the number of nodes on the contour $\partial\Omega_m$ times $2n$.

IV. APPLICATION EXAMPLE

The 2-D application example concerns a conducting cylinder (circular cross-section with radius R equal to 10 cm; conductivity σ equal to $6 \cdot 10^7$ S/m) placed inside an inductor (coil sides of rectangular cross-section) in which the current is imposed. Only one quarter of the geometry is modeled. See Figure 2. All materials are non-magnetic ($\mu = \mu_0 = 4\pi \cdot 10^{-7}$ H/m). The extension of space unto infinity is considered by means of a transformation method.

Figure 2 shows the very fine discretisation of the cylinder near its surface, allowing precise calculations with very small δ/R ratios (without using the SIBC). Flux patterns with $\delta/R = 0.5$ ($f = 1.69$ Hz) and $\delta/R = 0.1$ ($f = 42.2$ Hz) are depicted in Figure 3. When applying the SIBC, only the mesh outside the cylinder is effectively considered.

Fig. 2. FE model and mesh (1/4 of geometry) and detail of the FE mesh (the width of the outer layer of elements in the disk is equal to 0.3 mm, i.e. 0.3% of the radius R)

Fig. 3. Flux pattern (in phase with imposed sinusoidal current) with $\delta/R = 0.5$ (left) and $\delta/R = 0.1$ (right)

A. Frequency-domain results

The exact frequency-domain SIBC (28) has first been applied to our test case, with imposed sinusoidal current of unit amplitude and with δ/R ranging from 0.01 ($f = 4.2$ kHz) up to 1.5 ($f = 0.19$ Hz) approximately. The accurate results obtained with the so-called fine model (without SIBC) serve as reference. Figure 4 shows the real and imaginary part of the flux linkage of the inductor (normalized with the flux at 0 Hz). (Note that the imaginary part of the flux corresponds to the eddy-current losses in the cylinder, whereas its real part corresponds to the magnetic energy in the complete model.) We conclude from these results that the SIBC approach is accurate only if δ/R is smaller than 0.1.

We next adopt the low-order approximation of the SIBC, with $f_1 = 1$ kHz ($\delta_1/R = 0.02$) and further two discrete

Fig. 4. Real and imaginary part of normalized flux linkage as a function of skin depth, calculated with fine model and with exact SIBC

frequencies being odd multiples of f_1 , i.e. $f_2/f_1 = 3$ and $f_3/f_1 = 5$ (or $\delta_2/\delta_1 = 1/\sqrt{3}$ and $\delta_3/\delta_1 = 1/\sqrt{5}$). Figure 5 shows the real and imaginary part of the normalized flux linkage obtained with n equal to 1, 2 and 3.

Fig. 5. Real and imaginary part of normalized flux linkage as a function of skin depth, calculated with fine model, exact SIBC and low-order SIBCs

B. Time domain results

A trapezoidal current varying between 1 and -1 at 1 kHz is next considered. The current waveform together with the induction waveform in a point situated between the cylinder and the inductor are shown in Figure 6 for the first fundamental period (1 ms). For the low-order SIBCs, odd harmonics of $f_1 = 1$ kHz are considered, as above.

The magnetic energy and the joule losses in the cylinder have been calculated during the first period with the fine model (without SIBC) and the low-order SIBC (n equal to 1 and 2). A good convergence of the SIBC results towards the reference results is observed in Fig. 7.

V. CONCLUSIONS

The low-order SIBC approach presented in this paper is based on the resolution of the 1-D eddy-current problem in a semi-infinite slab considering a number of pairs of exponentially decreasing sine and cosine basis functions. The

Fig. 6. Current waveform and normalized induction in a point versus time obtained with fine model and time-domain SIBC approach

Fig. 7. Magnetic energy and joule losses in the cylinder versus time obtained with fine model and with time-domain approximation ($n = 1$ and $n = 2$)

choice of the associated discrete skin depths is application dependant but the stiffness and conductivity matrices to be evaluated for the application are essentially a function of the skin-depth ratios. The effectiveness of the SIBC approach has been clearly demonstrated with both frequency and time domain results.
