7 May 2017

#### Abstract

We further develop the Multivariate Decomposition Method (MDM) for the Lebesgue integration of functions of infinitely many variables $x_{1}, x_{2}, x_{3}, \ldots$ with respect to a corresponding product of a one dimensional probability measure. The method is designed for functions that admit a dominantly convergent decomposition $f=\sum_{\mathfrak{u}} f_{\mathfrak{u}}$, where $\mathfrak{u}$ runs over all finite subsets of positive integers, and for each $\mathfrak{u}=\left\{i_{1}, \ldots, i_{k}\right\}$ the function $f_{\mathfrak{u}}$ depends only on $x_{i_{1}}, \ldots, x_{i_{k}}$.

Although a number of concepts of infinite-dimensional integrals have been used in the literature, questions of uniqueness and compatibility have mostly not been studied. We show that, under appropriate convergence conditions, the Lebesgue integral equals the 'anchored' integral, independently of the anchor.

For approximating the integral, the MDM assumes that point values of $f_{\mathrm{u}}$ are available for important subsets $\mathfrak{u}$, at some known cost. In this paper we introduce a new setting, in which it is assumed that each $f_{\mathfrak{u}}$ belongs to a normed space $F_{\mathfrak{u}}$, and that bounds $B_{\mathfrak{u}}$ on $\left\|f_{\mathfrak{u}}\right\|_{F_{u}}$ are known. This contrasts with the assumption in many papers that weights $\gamma_{\mathfrak{u}}$, appearing in the norm of the infinite-dimensional function space, are somehow known. Often such weights $\gamma_{u}$ were determined by minimizing an error bound depending on the $B_{u}$, the $\gamma_{u}$ and the chosen algorithm, resulting in weights that depend on the algorithm. In contrast, in this paper only the bounds $B_{\mathfrak{u}}$ are assumed known. We give two examples in which we specialize the MDM: in the first case $F_{u}$ is the $|\mathfrak{u}|$-fold tensor product of an anchored reproducing kernel Hilbert space, and in the second case it is a particular non-Hilbert space for integration over an unbounded domain.

## 1 Introduction

This paper is intended as a contribution, both theoretical and practical, to the challenging task of numerical integration of multivariate functions, when the number of variables is large, and even infinite.

High-dimensional integration has emerged in recent years as a significant new direction for numerical computation, see [11]. On the one hand the improved processing power of computers has encouraged the practical computation of multivariate integrals with very large numbers of variables, into the hundreds or thousands or tens of thousands. On the other hand such problems will never become trivial - indeed, many important high-dimensional problems (see below for an example) contain parameters for which physically interesting choices can lead to problems of unlimited difficulty.

Many papers have been written in recent decades about high-dimensional integration, see the reviews [3] for sparse grid methods and [10] for Quasi-Monte Carlo methods, and their many references.

In many applications the number of variables is not merely large but in principle infinite. This is the case in the important class of problems of elliptic partial differential equations with uncertain coefficients. A key example is Darcy flow through a porous medium with highly variable permeability (see e.g., [18]), with the permeability modelled as a random field. Since a continuous random field requires an infinite number of scalar random variables for its description, the expected value of any property of the flow is in principle an infinite-dimensional integral. Of course in practice the infinitedimensional integral has to be truncated to a finite-dimensional integral, but if the correlation length
of the permeability field is small, or the variance is large, then the dimensionality might need to be very large indeed to capture the essential physics.

Some other recent papers devoted to infinite-dimensional integration are $[1,2,5-7,13-16,21,22,28$, $30,31,34-36,41-45,47-49]$.

The theoretical setting in most of these papers (and the theoretical setting is of key importance, given the general lack of useful intuition in high dimensions) has been that of "weighted" reproducing kernel Hilbert spaces, where the weights enter the norm of the function space. Often the spaces are tensor products of one-dimensional reproducing kernel Hilbert spaces, and the "weights" are of the "product" kind introduced by Sloan and and Woźniakowski [38], in which there is one weight $\gamma_{j}$ for each variable $x_{j}$, with $\gamma_{1} \geq \gamma_{2} \geq \cdots>0$, with the decreasing weights reflecting the decreasing importance of the successive variables. This has been extended to "general weights", in which case there is a potentially different non-negative weight $\gamma_{\mathfrak{u}}$ for each finite subset $\mathfrak{u}$ of the natural numbers; the product weight case is then recovered by setting $\gamma_{\mathfrak{u}}=\prod_{j \in \mathfrak{u}} \gamma_{j}$. In these papers it is assumed that the integrand is expressible in the form

$$
\begin{equation*}
f(\boldsymbol{x})=\sum_{|\mathfrak{u}|<\infty} f_{\mathfrak{u}}(\boldsymbol{x})=\sum_{|\mathfrak{u}|<\infty} f_{\mathfrak{u}}\left(\boldsymbol{x}_{\mathfrak{u}}\right) \tag{1}
\end{equation*}
$$

where the sum (see also (3) below) is over all finite subsets $\mathfrak{u} \subset \mathbb{N}:=\{1,2, \ldots\}$, with $|\mathfrak{u}|$ denoting the cardinality of $\mathfrak{u}$, and each function $f_{\mathfrak{u}}$ depends only on the subset of the variables in $\mathfrak{u}$ and we write $\boldsymbol{x}_{\mathfrak{u}}:=\left\{x_{j}: j \in \mathfrak{u}\right\}$. Furthermore, $f_{\mathfrak{u}}$ is assumed to belong to a normed space $F_{\mathfrak{u}}$, which is usually a reproducing kernel Hilbert space. The weights determine the importance of different subsets $\mathfrak{u}$ through their appearance in a norm of the form

$$
\begin{equation*}
\left(\sum_{|\mathfrak{u}|<\infty}\left(\frac{\left\|f_{\mathfrak{u}}\right\|_{F_{\mathfrak{u}}}}{\gamma_{\mathfrak{u}}}\right)^{q}\right)^{1 / q} \tag{2}
\end{equation*}
$$

in which case the function $f$ belongs to a Banach space $\mathcal{F}=\mathcal{F}_{\gamma, q}$. Commonly $q=2$, in which case $\mathcal{F}$ is a Hilbert space, and some papers replace $\gamma_{\mathfrak{u}}$ by $\gamma_{\mathfrak{u}}^{1 / 2}$.

Throughout this paper we shall use the convention that in infinite sums over subsets as in (1) and (2) the terms are to be ordered in terms of increasing truncation dimension,

$$
\begin{equation*}
\sum_{|\mathfrak{u}|<\infty} f_{\mathfrak{u}}(\boldsymbol{x}):=\lim _{d \rightarrow \infty} \sum_{\mathfrak{u} \subseteq\{1, \ldots, d\}} f_{\mathfrak{u}}(\boldsymbol{x}) \tag{3}
\end{equation*}
$$

with the additional subsets when $d$ increases to $d+1$ ordered as for the case $d$ with respect to the original members.

The Multivariate Decomposition Method (MDM) proposed in [35, 43, 44] is a generalisation of the Changing Dimension Algorithm in [28, 34]. Here too it is assumed that an expansion of the form (1) exists, and that values of $f_{\mathfrak{u}}\left(\boldsymbol{x}_{\mathfrak{u}}\right)$, while not available explicitly, can be obtained by a modest number of evaluations of $f(\boldsymbol{x})$. In Section 5 we give specific examples in which values of $f_{\mathfrak{u}}\left(\boldsymbol{x}_{\mathfrak{u}}\right)$ can be obtained from at most $2^{|\mathfrak{u}|}$ evaluations of $f(\boldsymbol{x})$ - an acceptably small number if the cardinality $|\mathfrak{u}|$ is small.

In previous MDM papers $[35,43,44]$ the norm was assumed to be of the form (2). In the present paper, in contrast, we do not assume that weights $\gamma_{\mathfrak{u}}$ are given as a priori information. Rather, we assume that the terms $f_{\mathfrak{u}}$ in the expansion (1) belong to normed function spaces $F_{\mathfrak{u}}$, and crucially, that upper bounds on the norms $\left\|f_{\mathfrak{u}}\right\|_{F_{\mathfrak{u}}}$ are known, i.e., that for $|\mathfrak{u}|<\infty$ numbers $B_{\mathfrak{u}}$ satisfying

$$
\begin{equation*}
\left\|f_{\mathfrak{u}}\right\|_{F_{\mathfrak{u}}} \leq B_{\mathfrak{u}} \tag{4}
\end{equation*}
$$

are given as a priori information. This new setting is equivalent to putting $q=\infty$ and $\gamma_{\mathfrak{u}}=B_{\mathfrak{u}}$ in (2), but in all other cases the two approaches are not equivalent. Given the bounds $B_{\mathfrak{u}}$, one is of course
free to select a value of $q$ and a set of weights $\gamma_{u}$ that make (2) finite, but in neither case is the choice unique, or is one choice obviously better than another. In the present work we make no explicit use of weights.

The advantage of the current setting, in which bounds $B_{\mathfrak{u}}$ rather than weights $\gamma_{u}$ are specified, lies in its immediate applicability once such bounds are known. We note that a number of recent papers have provided directly useable bounds $B_{\mathrm{u}}$ : for partial differential equations with random coefficients, see [4] for the case of uniformly distributed stochastic variables, and [17,20] for the lognormal case; and for generalized response models in statistics, see [37]. It seems likely that similar bounds will be found for other applications in the future. In contrast, in practical situations it is typically not clear how to choose weights $\gamma_{u}$, or product weights $\gamma_{j}$. We recall that weights were originally introduced (in [38]) to provide a setting in which the tractability of multivariate integration (roughly, to know what happens to the worst-case error as $d \rightarrow \infty$ ) could be studied. Never was it claimed that weights were naturally available in an application. Some recent papers have obtained formulas for suitable weights, but these "optimal weights" are deduced by minimising an error bound which depends on the $B_{\mathfrak{u}}$, the $\gamma_{\mathfrak{u}}$ and the chosen algorithm. See $[26,27]$ and $[17,24]$ for the PDE with random coefficients and randomly shifted lattice rules in the uniform and lognormal cases respectively, and $[8,9]$ for the uniform case with higher order digital nets, as well as [23] for a survey of these results. The dependence of weights on the algorithm is unacceptable from the point of view of information based complexity, where the complexity of the problem (i.e., integration in $\mathcal{F}_{\gamma, q}$, specified by (2), and thus depending on the $\gamma_{u}$ ) is supposed to be studied independently of any algorithm. In contrast, we believe that the present setting will provide a robust basis not only for the development of computational schemes, but also for future complexity and tractability studies of high-dimensional integration.

The problem to be considered is that of integration over an infinite-dimensional product region,

$$
\begin{equation*}
\mathcal{I}(f):=\int_{D^{\mathbb{N}}} f(\boldsymbol{x}) \mathrm{d} \mu(\boldsymbol{x}), \tag{5}
\end{equation*}
$$

where the integral is in the Lebesgue sense. Here $\mu$ is the countable product, $\mu=\times_{j=1}^{\infty} \mu_{1}$, of a onedimensional probability measure $\mu_{1}$ defined on a Borel set $D \subseteq \mathbb{R}$, and $D^{\mathbb{N}}$ is the set of all infinite sequences $\boldsymbol{x}=\left(x_{1}, x_{2}, x_{3}, \ldots\right)$ with $x_{j} \in D$. We assume that $\mu_{1}$ is determined by a probability density $\rho$ on $D$.

At this point it is worth mentioning that many papers define the infinite-dimensional integral as

$$
\begin{equation*}
\mathcal{I}_{a}(f):=\lim _{d \rightarrow \infty} \int_{D^{d}} f\left(x_{1}, \ldots, x_{d}, a, a, \ldots\right) \mathrm{d} \mu_{d}\left(x_{1}, \ldots, x_{d}\right), \tag{6}
\end{equation*}
$$

where $\mu_{d}=\times_{j=1}^{d} \mu_{1}$, for some fixed $a \in D$, usually with the 'anchor' taken as $a=0$. Taken on its own that definition seems open to question if the value of the integral could depend on the choice of the anchor $a$. We address this uniqueness concern in Section 2, where sufficient conditions are given to ensure that the equality $\mathcal{I}(f)=\mathcal{I}_{a}(f)$ holds independently of the choice of $a$.

To approximate the integral (5), the MDM uses the decomposition of $f$ given in (1). Indeed, assuming that the partial sums in (3) converge dominantly to $f$, we have

$$
\begin{equation*}
\mathcal{I}(f)=\lim _{d \rightarrow \infty} \sum_{\mathfrak{u} \subseteq\{1, \ldots, d\}} \int_{D^{|\mathfrak{u}|}} f_{\mathfrak{u}}\left(\boldsymbol{x}_{\mathfrak{u}}\right) \mathrm{d} \mu_{|\mathfrak{u}|}\left(\boldsymbol{x}_{\mathfrak{u}}\right)=: \lim _{d \rightarrow \infty} \sum_{\mathfrak{u} \subseteq\{1, \ldots, d\}} I_{\mathfrak{u}}\left(f_{\mathfrak{u}}\right)=\sum_{|\mathfrak{u}|<\infty} I_{\mathfrak{u}}\left(f_{\mathfrak{u}}\right) . \tag{7}
\end{equation*}
$$

The essence of MDM is that a separate quadrature rule (which in all but a finite number of cases will be the zero approximation) is applied to each term $f_{u}$ in the decomposition of $f$. In more detail, the overall algorithm $\mathcal{A}_{\varepsilon}$ for approximating $\mathcal{I}(f)$ up to an error request $\varepsilon$ has the form

$$
\begin{equation*}
\mathcal{A}_{\varepsilon}(f):=\sum_{\mathfrak{u} \in \mathcal{U}(\varepsilon)} A_{\mathfrak{u}, n_{\mathfrak{u}}}\left(f_{\mathfrak{u}}\right):=\sum_{\mathfrak{u} \in \mathcal{U}(\varepsilon)} \sum_{i=1}^{n_{\mathfrak{u}}} w_{\mathfrak{u}, i} f_{\mathfrak{u}}\left(\boldsymbol{x}_{\mathfrak{u}, i}\right), \tag{8}
\end{equation*}
$$

where the active set $\mathcal{U}(\varepsilon)$ is a finite set of finite subsets of $\mathbb{N}$, and $n_{\mathfrak{u}}, \boldsymbol{x}_{\mathfrak{u}, i}$ and $w_{\mathfrak{u}, i}$ are parameters of the quadrature rule $A_{\mathfrak{u}, n_{\mathfrak{u}}}$. In effect, the contributions to $\mathcal{I}(f)$ from terms $f_{\mathfrak{u}}$ with $\mathfrak{u}$ outside the active set are approximated by zero and thus the construction of $\mathcal{U}(\varepsilon)$ depends on the error request $\varepsilon$. We note that both the active set $\mathcal{U}(\varepsilon)$ and the algorithm $\mathcal{A}_{\varepsilon}$ are intended to be independent of the particular function $f \in \mathcal{F}$ once the bounds $B_{\mathfrak{u}}$ are provided.

Clearly, the selection of the active set $\mathcal{U}(\varepsilon)$ and the determination of the quadrature rules $A_{u, n_{\mathrm{u}}}$ for $\mathfrak{u} \in \mathcal{U}(\varepsilon)$ are key ingredients of the MDM. To make the selections in a rational way we need to assume not only that we have a priori information about the size of the terms $f_{\mathfrak{u}}$ in the expansion of $f$ in the form of the upper bounds $B_{\mathfrak{u}}$, but also that we are provided with suitable information about the difficulty of the integration problem and the quality of the quadrature rules in $F_{\mathfrak{u}}$.

For two specific applications, we develop an MDM whose worst-case error is upper bounded by $\varepsilon^{1-\delta(\varepsilon)}$ and the information cost is proportional to $(1 / \varepsilon)^{1+\delta(\varepsilon)}$ where $\delta(\varepsilon)>0$ and $\delta(\varepsilon) \rightarrow 0$, under quite general assumptions about the bounds $B_{\mathfrak{u}}$ and the cost of function evaluations. This means that for the given application the MDM is almost optimal since even for the corresponding space of univariate functions, the minimal cost of computing an $\varepsilon$-approximation is proportional to $1 / \varepsilon$ for these two applications.

The content of the paper is as follows. In Section 2 we discuss relations between the Lebesgue and 'anchored' integrals. Then in Section 3 we describe the setting for the MDM and in Section 4 we develop the MDM in its general form. Then in Section 5 we turn to an important application, one that provides the initial motivation for the method. This is the case of the so-called "anchored decomposition" associated with anchored reproducing kernel Hilbert spaces, which have very often been used in studies of multivariate integration and approximation. We shall see that in this case all the assumptions of the MDM are satisfied, and that there is a significant class of integration problems for which the MDM can be highly efficient. In Section 6 we consider another application, this one of a non-Hilbert space nature. Efficient implementation of MDM will be considered in a forthcoming paper [12].

## 2 Lebesgue integral and 'anchored' integral

In this section, we compare the Lebesgue integral (5) with the 'anchored' integral (6) and show in particular that, under suitable assumptions, they are equivalent.

Recall that $D$ is a Borel subset of $\mathbb{R}$ and $D^{\mathbb{N}}$, where $\mathbb{N}=\{1,2,3, \ldots\}$, is the set of all infinite sequences/points $\boldsymbol{x}=\left(x_{1}, x_{2}, x_{3}, \ldots\right)$ with each $x_{j} \in D$. Furthermore, $\mu_{1}$ is a probability measure on the Borel $\sigma$-field of $D$, and we denote by $\mu_{d}=\times_{j=1}^{d} \mu_{1}$ the $d$-product of $\mu_{1}$ on $D^{d}$, and by $\mu=\times_{j=1}^{\infty} \mu_{1}$ the countable product of $\mu_{1}$ on $D^{\mathbb{N}}$. By Lebesgue integral of a function $f: D^{\mathbb{N}} \rightarrow \mathbb{R}$ we mean the integral with respect to $\mu$, and a.e. means almost everywhere with respect to $\mu$.

In general, the Lebesgue and 'anchored' integrals are quite different. Moreover, 'anchored' integrals may depend on $a$. A simple example is provided by the function $f: \mathbb{R}^{\mathbb{N}} \rightarrow \mathbb{R}$ such that $f(\boldsymbol{x})=0$ if $\boldsymbol{x}$ has only finitely many non-zero coordinates, and $f(\boldsymbol{x})=1$ otherwise. Indeed, then the limit in (6) is 0 for $a=0$, and 1 for $a=1$. On the other hand, for the integral (5) we have $\mathcal{I}(f)=1$.

The following well-known Lebesgue's dominated convergence theorem, see, e.g., [19, Sect. 26], will play an important role in our considerations.

Theorem 1 Let $\left\{f_{d}\right\}_{d \geq 0}$ be a sequence of integrable functions that converges dominantly to $f$, i.e.,
(i) $\lim _{d \rightarrow \infty} f_{d}(\boldsymbol{x})=f(\boldsymbol{x})$ for $\boldsymbol{x}$ a.e.
(ii) for some integrable function $g$ we have $\left|f_{d}(\boldsymbol{x})\right| \leq|g(\boldsymbol{x})|$ for $\boldsymbol{x}$ a.e.

Then

$$
\begin{equation*}
\mathcal{I}(f)=\lim _{d \rightarrow \infty} \mathcal{I}\left(f_{d}\right) . \tag{9}
\end{equation*}
$$

Theorem 1 can be directly applied to a variety of sequences $\left\{f_{d}\right\}_{d \geq 0}$. It implies, in particular, that if the functions $f_{u}$ in the decomposition (1) are integrable and

$$
\begin{equation*}
f_{d}:=\sum_{\mathfrak{u} \subseteq\{1, \ldots, d\}} f_{\mathfrak{u}} \tag{10}
\end{equation*}
$$

converge dominantly to $f$, then the integral can be computed using the equality

$$
\mathcal{I}(f)=\lim _{d \rightarrow \infty} \sum_{\mathfrak{u} \subseteq\{1, \ldots, d\}} \int_{D|\mathfrak{u}|} f_{\mathfrak{u}}\left(\boldsymbol{x}_{\mathfrak{u}}\right) \mathrm{d} \mu_{|\mathfrak{u}|}\left(\boldsymbol{x}_{\mathfrak{u}}\right) .
$$

(We will use this fact later in the MDM.) Similarly, for fixed $\boldsymbol{a}=\left(a_{1}, a_{2}, a_{3}, \ldots\right) \in D^{\mathbb{N}}$ we have

$$
\begin{equation*}
\mathcal{I}(f)=\mathcal{I}_{\boldsymbol{a}}(f):=\lim _{d \rightarrow \infty} \int_{D^{d}} f\left(x_{1}, \ldots, x_{d}, a_{d+1}, a_{d+2}, \ldots\right) \mathrm{d} \mu_{d}\left(x_{1}, \ldots, x_{d}\right) \tag{11}
\end{equation*}
$$

if the functions

$$
\begin{equation*}
D^{\mathbb{N}} \ni \boldsymbol{x}=\left(x_{1}, x_{2}, x_{3}, \ldots\right) \mapsto f\left(x_{1}, \ldots, x_{d}, a_{d+1}, a_{d+2}, \ldots\right) \tag{12}
\end{equation*}
$$

are integrable and converge dominantly to $f$. That is, we then have equivalence of the Lebesgue and 'anchored' integrals for the anchor $\boldsymbol{a}$.

The following result allows us to claim that such equivalence holds for all anchors after checking only one sequence, e.g., $f_{d}(\boldsymbol{x})=f\left(x_{1}, \ldots, x_{d}, a, a, a, \ldots\right)$ for an $a \in D$. The sufficient condition is however stronger than that in Theorem 1.

Theorem 2 Let $\left\{f_{d}\right\}_{d \geq 0}$ be a sequence of integrable functions converging dominantly to $f$, such that each $f_{d}$ depends only on the variables $x_{1}, \ldots, x_{d}$. Let, in addition, the convergence be uniform a.e., or the following less restrictive assumption be satisfied: for $\boldsymbol{x}=\left(x_{1}, x_{2}, x_{3}, \ldots\right)$ a.e.

$$
\begin{equation*}
\left|f_{d}(\boldsymbol{x})-f(\boldsymbol{x})\right| \leq g_{d}\left(x_{1}, \ldots, x_{d}\right) \quad \forall d \geq 0 \tag{13}
\end{equation*}
$$

for some sequence $\left\{g_{d}\right\}_{d \geq 0}$ of integrable functions that converges dominantly to the zero function. Then (11) holds for $\boldsymbol{a}=\left(a_{1}, a_{2}, a_{3}, \ldots\right)$ a.e.

Moreover, if (13) holds for all $\boldsymbol{x} \in D^{\mathbb{N}}$ then (11) holds for all anchors $\boldsymbol{a} \in D^{\mathbb{N}}$ provided the functions (12) are measurable.

Proof. By dominated convergence of $\left\{f_{d}\right\}_{d \geq 0}$ we know that $f$ is integrable.
Let $\mathcal{D}_{1}$ be the set of all points $\boldsymbol{a}=\left(a_{1}, a_{2}, a_{3}, \ldots\right)$ for which the functions (12) are measurable for all $d \geq 0$. We show that $\mu\left(\mathcal{D}_{1}\right)=1$. Indeed, since $f$ is measurable and $\mu$ is a product measure, $\mu=\mu_{d} \times \mu$, it follows that for any fixed $d$ the measure of $\left(a_{d+1}, a_{d+2}, \ldots\right)$ such that the functions (12) are measurable is 1 . Hence $\mu\left(\mathcal{D}_{1}\right)=1$ as an intersection of countably many sets of measure 1 .

Let $\mathcal{D}_{2}$ consist of all $\boldsymbol{a}$ for which

$$
\begin{equation*}
\mu\left(\left\{\boldsymbol{x}:\left|f_{d}(\boldsymbol{x})-f\left(x_{1}, \ldots, x_{d}, a_{d+1}, a_{d+2}, \ldots\right)\right| \leq g_{d}\left(x_{1}, \ldots, x_{d}\right) \forall d \geq 0\right\}\right)=1 \tag{14}
\end{equation*}
$$

Then $\mu\left(\mathcal{D}_{2}\right)=1$ as well. Indeed, denote by $\mathcal{D}$ the collection of all $\boldsymbol{x}$ for which (13) holds. Since $\mu(\mathcal{D})=1$, using again the argument that $\mu$ is a product measure, we obtain, for $\boldsymbol{a}$ a.e. and fixed $d \geq 0$, that
$\mu\left(\left\{\boldsymbol{x}:\left(x_{1}, \ldots, x_{d}, a_{d+1}, a_{d+2}, \ldots\right) \in \mathcal{D}\right\}\right)=\mu_{d}\left(\left\{\left(x_{1}, \ldots, x_{d}\right):\left(x_{1}, \ldots, x_{d}, a_{d+1}, a_{d+2}, \ldots\right) \in \mathcal{D}\right\}\right)=1$.
Since $\mathcal{D}_{2}$ is the countable intersection of these sets, it follows that $\mu\left(\mathcal{D}_{2}\right)=1$. Concluding this part of the proof we have that $\mu\left(\mathcal{D}_{1} \cap \mathcal{D}_{2}\right)=1$.

Now let $\boldsymbol{a} \in \mathcal{D}_{1} \cap \mathcal{D}_{2}$. Then for $\boldsymbol{x}$ a.e.

$$
\begin{aligned}
\left|f(\boldsymbol{x})-f\left(x_{1}, \ldots, x_{d}, a_{d+1}, a_{d+2}, \ldots\right)\right| & \leq\left|f_{d}(\boldsymbol{x})-f(\boldsymbol{x})\right|+\left|f_{d}(\boldsymbol{x})-f\left(x_{1}, \ldots, x_{d}, a_{d+1}, a_{d+2}, \ldots\right)\right| \\
& \leq 2 g_{d}\left(x_{1}, \ldots, x_{d}\right),
\end{aligned}
$$

and by dominated convergence of $\left\{g_{d}\right\}_{d \geq 0}$ to the zero function, it follows that

$$
\lim _{d \rightarrow \infty} \int_{D^{\mathbb{N}}}\left|f(\boldsymbol{x})-f\left(x_{1}, \ldots, x_{d}, a_{d+1}, a_{d+2}, \ldots\right)\right| \mathrm{d} \mu(\boldsymbol{x}) \leq 2 \lim _{d \rightarrow \infty} \int_{D^{d}} g_{d}\left(x_{1}, \ldots, x_{d}\right) \mathrm{d} \mu_{d}\left(x_{1}, \ldots, x_{d}\right)=0
$$

which implies (11) for $\boldsymbol{a}$ a.e.
To show the remaining part of the theorem, observe that the actual set of anchors $\boldsymbol{a}$ for which we have equivalence of the Lebesgue and 'anchored' integrals includes $\mathcal{D}_{1} \cap \mathcal{D}_{2}$. Under the additional assumptions we obviously have $\mathcal{D}_{1}=D^{\mathbb{N}}$ and $\mathcal{D}_{2}=D^{\mathbb{N}}$. Hence $\mathcal{D}_{1} \cap \mathcal{D}_{2}=D^{\mathbb{N}}$, as claimed.

Example 3 For $D=[-\alpha, \alpha]$ or $D=\mathbb{R}$, consider

$$
\begin{equation*}
f\left(x_{1}, x_{2}, \ldots\right):=\sum_{j=1}^{\infty} \lambda_{j} x_{j}^{2} \tag{15}
\end{equation*}
$$

where $\lambda_{j}>0 \forall j$ and $\sum_{j=1}^{\infty} \lambda_{j}<\infty$, and assume that $E:=\int_{D} x^{2} \mathrm{~d} \mu_{1}<\infty$. The function $f$ is well defined since even in case $D=\mathbb{R}$ (where $\mu_{1}$ could be Gaussian) the set of sequences $\left(x_{1}, x_{2}, \ldots\right) \in \mathbb{R}^{\mathbb{N}}$ for which the sum (15) is finite is of measure one. The Lebesgue integral equals

$$
\mathcal{I}(f)=\sum_{j=1}^{\infty} \int_{D} \lambda_{j} x_{j}^{2} \mathrm{~d} \mu_{1}=E \sum_{j=1}^{\infty} \lambda_{j} .
$$

On the other hand, for the 'anchored' integral with $\boldsymbol{a}=\left(a_{1}, a_{2}, a_{3}, \ldots\right)$ we have

$$
\int_{D^{d}} f\left(x_{1}, \ldots, x_{d}, a_{d+1}, a_{d+2}, \ldots\right) \mathrm{d} \mu_{d}\left(x_{1}, \ldots, x_{d}\right)=E \sum_{j=1}^{d} \lambda_{j}+\sum_{j=d+1}^{\infty} \lambda_{j} a_{j}^{2},
$$

which converges to $\mathcal{I}(f)$ if and only if

$$
\begin{equation*}
\sum_{j=1}^{\infty} \lambda_{j} a_{j}^{2}<\infty \tag{16}
\end{equation*}
$$

The inequality (16) is a necessary and sufficient condition for $\mathcal{I}(f)=\mathcal{I}_{\boldsymbol{a}}(f)$. It holds for all $\boldsymbol{a}$ if $D=[-\alpha, \alpha]$, and for $\boldsymbol{a}$ a.e. if $D=\mathbb{R}$. We also observe that assumptions of Theorem 2 are satisfied with, e.g.,

$$
f_{d}(\boldsymbol{x})=f\left(x_{1}, \ldots, x_{d}, 0,0,0, \ldots\right)=\sum_{j=1}^{d} \lambda_{j} x_{j}^{2} \quad \text { and } \quad g_{d} \equiv \alpha^{2} \sum_{j=d+1}^{\infty} \lambda_{j}
$$

only if $D$ is a finite interval, and then the convergence is uniform on the whole domain $D^{\mathbb{N}}$.

## 3 The setting for MDM

We provide in this section basic assumptions concerning the approximate integration problem considered in this paper. In particular, we will introduce standing assumptions (A1)-(A6) that pertain to the whole paper. As we shall see later, the assumptions are satisfied by a number of specific problems.

### 3.1 The function class $\mathcal{F}$

We introduce a class $\mathcal{F}$ of $\infty$-variate real-valued functions whose integrals are to be approximated. For a finite subset $\mathfrak{u} \subset \mathbb{N}$ and a point $\boldsymbol{x} \in D^{\mathbb{N}}, \boldsymbol{x}_{\mathfrak{u}}$ denotes the variables $x_{j}$ with $j \in \mathfrak{u}$, and $D^{\mathfrak{u}}$ denotes the product integration region $D^{|\mathfrak{u}|}$ with the variables replaced by those in $\boldsymbol{x}_{\mathfrak{u}}$, where $|\mathfrak{u}|$ denotes the cardinality of $\mathfrak{u}$.

As in the Introduction, functions in the class $\mathcal{F}$ are expressed as sums of functions $f_{\mathfrak{u}}$, with $f_{\mathfrak{u}}$ depending only on the variables in $\boldsymbol{x}_{\mathfrak{u}}$ and belonging to a normed linear space $F_{\mathfrak{u}}$.
(A1) Each $f \in \mathcal{F}$ has a decomposition of the form (1) where the sums over all finite subsets $\mathfrak{u} \subset \mathbb{N}$ are defined as in (3), and each $f_{\mathfrak{u}}$ is formally a function on $D^{\mathbb{N}}$ but depends only on the variables $x_{j}$ with $j \in \mathfrak{u}$. The functions $f_{d}$ defined in (10) are assumed to be dominantly (or even uniformly) convergent to $f$.
(A2) Each component $f_{\mathfrak{u}}$ of $f$ in (1) belongs to a normed space $F_{\mathfrak{u}}$ of real-valued measurable functions defined on $D^{\mathfrak{u}}$ with norm $\left\|f_{u}\right\|_{F_{\mathfrak{u}}}$. Moreover, $\left\|f_{\mathfrak{u}}\right\|_{F_{\mathfrak{u}}} \leq B_{\mathfrak{u}}$, see (4), for known positive numbers $B_{\mathfrak{u}}$. In particular, $F_{\emptyset}$ is the space of constant functions with norm given by the absolute value. Finally, point evaluation at any $\boldsymbol{x}_{\mathfrak{u}} \in D^{\mathfrak{u}}$ is assumed to be a continuous linear functional on $F_{\mathfrak{u}}$.

We shall see later in Sections 5 and 6 concrete examples of the function class $\mathcal{F}$.

### 3.2 The integration problem

As in (7), we express an infinite-dimensional integral $\mathcal{I}(f)$ for $f \in \mathcal{F}$ as a sum of multivariate integrals $I_{\mathfrak{u}}\left(f_{\mathfrak{u}}\right)$ from the decomposition $f=\sum_{|u|<\infty} f_{\mathfrak{u}}$. Recalling that $\rho$ is a given probability density function on $D$, we write $\rho_{\mathfrak{u}}\left(\boldsymbol{x}_{\mathfrak{u}}\right):=\prod_{j \in \mathfrak{u}} \rho\left(x_{j}\right)$. For $\mathfrak{u}=\emptyset$, we set $I_{\emptyset}\left(f_{\emptyset}\right):=f_{\emptyset}$. We make the following assumption.
(A3) All functions in $F_{\mathfrak{u}}$ are Lebesgue measurable and integrable with respect to $\rho_{\mathfrak{u}}\left(\boldsymbol{x}_{\mathfrak{u}}\right) \mathrm{d} \boldsymbol{x}_{\mathfrak{u}}$, and the functionals $I_{u}$ are continuous, i.e.,

$$
\begin{equation*}
C_{\mathfrak{u}}:=\left\|I_{\mathfrak{u}}\right\|=\sup _{\left\|f_{u}\right\| F_{\mathfrak{u}} \leq 1}\left|\int_{D^{|\mathfrak{u}|}} f_{\mathfrak{u}}\left(\boldsymbol{x}_{\mathfrak{u}}\right) \rho_{\mathfrak{u}}\left(\boldsymbol{x}_{\mathfrak{u}}\right) \mathrm{d} \boldsymbol{x}_{\mathfrak{u}}\right|<\infty . \tag{17}
\end{equation*}
$$

At this moment, we also assume that the numbers $B_{\mathfrak{u}}$ in (4) and $C_{\mathfrak{u}}$ in (17) satisfy

$$
\begin{equation*}
\sum_{|\mathfrak{u}|<\infty} C_{\mathfrak{u}} B_{\mathfrak{u}}<\infty \tag{18}
\end{equation*}
$$

which will later be replaced by a stronger assumption (A4). Since $\left|I_{\mathfrak{u}}\left(f_{\mathfrak{u}}\right)\right| \leq\left\|I_{\mathfrak{u}}\right\|\left\|f_{\mathfrak{u}}\right\|_{F_{\mathfrak{u}}} \leq C_{\mathfrak{u}} B_{\mathfrak{u}}$, the condition (18) implies that the sum $\sum_{|\mathfrak{u}|<\infty}\left|I_{\mathfrak{u}}\left(f_{\mathfrak{u}}\right)\right|$ is finite. Moreover,

$$
\sup _{f \in \mathcal{F}}|\mathcal{I}(f)| \leq \sum_{|\mathfrak{u}|<\infty} C_{\mathfrak{u}} B_{\mathfrak{u}}<\infty .
$$

We end this subsection with the following remark.
Remark 4 Instead of assuming convergence in (A1), we can impose conditions on the point evaluation functionals as follows. Let $L_{\mathfrak{u}, \boldsymbol{x}_{\mathfrak{u}}}$ be the point evaluation functional on $F_{\mathfrak{u}}, L_{\mathfrak{u}, \boldsymbol{x}_{\mathfrak{u}}}\left(f_{\mathfrak{u}}\right)=f_{\mathfrak{u}}\left(\boldsymbol{x}_{\mathfrak{u}}\right)$. Assume that for every $\mathfrak{u}$, we have $\mathcal{L}_{\mathfrak{u}}:=\sup _{\boldsymbol{x}_{\mathfrak{u}}}\left\|L_{\mathfrak{u}, \boldsymbol{x}_{\mathfrak{u}}}\right\|<\infty$ and

$$
\begin{equation*}
\sum_{|\mathfrak{u}|<\infty} \mathcal{L}_{\mathfrak{u}} B_{\mathfrak{u}}<\infty . \tag{19}
\end{equation*}
$$

Then $\left|\sum_{|\mathfrak{u}|<\infty} f_{\mathfrak{u}}\left(\boldsymbol{x}_{\mathfrak{u}}\right)\right| \leq \sum_{|\mathfrak{u}|<\infty}\left|L_{\mathfrak{u}, \boldsymbol{x}_{\mathfrak{u}}}\left(f_{\mathfrak{u}}\right)\right| \leq \sum_{|\mathfrak{u}|<\infty} \mathcal{L}_{\mathfrak{u}}\left\|f_{\mathfrak{u}}\right\|_{F_{\mathfrak{u}}} \leq \sum_{|\mathfrak{u}|<\infty} \mathcal{L}_{\mathfrak{u}} B_{\mathfrak{u}}<\infty$; that is, we have uniform convergence on the whole domain $D^{\mathbb{N}}$. Hence, defining the class

$$
\mathcal{F}^{*}:=\left\{\sum_{|\mathfrak{u}|<\infty} f_{\mathfrak{u}}:\left\|f_{\mathfrak{u}}\right\|_{F_{\mathfrak{u}}} \leq B_{\mathfrak{u}}\right\}
$$

we have by Theorem 2 that for any $f$ in $\mathcal{F}^{*}$ the Lebesgue integral equals the 'anchored' integral for any anchor, and the integral can be expressed by any decomposition.

For spaces $F_{\mathfrak{u}}$ being the $|\mathfrak{u}|$-fold tensor products of some space $F_{\{1\}}$ of univariate functions, we often have that $C_{\mathfrak{u}}=C_{\{1\}}^{|u|}$ and $\mathcal{L}_{\mathfrak{u}}=\mathcal{L}_{\{1\}}^{|\mathfrak{u}|}$. Then for many families of bounds $B_{\mathfrak{u}}$, including bounds of the form (37) to be discussed later, it is known that (see Lemma 10 below) (18) is equivalent to (19) which in turn is equivalent to

$$
\sum_{|u|<\infty} B_{\mathfrak{u}}<\infty .
$$

### 3.3 Examples of decompositions

In practice one can expect to be given the $\infty$-variate function $f$, the integration domain $D^{\mathbb{N}}$ and the weight function $\rho$, after which it is the user's task to define a suitable sequence of normed spaces $F_{\mathbf{u}}$ and a method of decomposing $f$ into components $f_{\mathfrak{u}} \in F_{\mathfrak{u}}$.

Example 5 The following $\infty$-variate problem is a variant of a simpler model problem introduced in [25, Section 1.5], which in turn is modeled on a study [26] of a diffusion problem for the flow of a liquid through a porous medium treated as a random permeability field. In this example we have

$$
\begin{equation*}
D:=\left[-\frac{1}{2}, \frac{1}{2}\right], \quad \rho(x):=1, \quad f(\boldsymbol{x}):=\frac{1}{1+\sum_{j=1}^{\infty} x_{j} / j^{2}} \tag{20}
\end{equation*}
$$

For the space $F_{\mathfrak{u}}$ we here choose for simplicity a Hilbert space. Given the requirement that point evaluation be a continuous linear functional, we choose the simplest Hilbert space available to us, namely

$$
F_{\mathfrak{u}}:=H^{1, \ldots, 1}:=\bigotimes_{j \in \mathfrak{u}} H^{1},
$$

with the conventional Sobolev-type norm

$$
\|g\|_{F_{\mathbf{u}}}:=\left(\sum_{\alpha \leq(1, \ldots, 1)}\left\|\mathcal{D}^{\alpha} g\right\|_{L_{2}\left(D^{u}\right)}^{2}\right)^{1 / 2}
$$

where the sum is over all multi-indices $\boldsymbol{\alpha}$ with components $\alpha_{j} \in\{0,1\}$ for $j \in \mathfrak{u}$, and $\mathcal{D}^{\boldsymbol{\alpha}}$ denotes the appropriate weak mixed derivative.

This choice of the normed spaces $F_{\mathfrak{u}}$ allows many different decompositions. To illustrate this point, let us first confine our attention to so-called "anchored" decompositions (see e.g., [29] and later), with anchor at some fixed $a \in D$. That is, for $f \in \mathcal{F}$ the terms $f_{\mathfrak{u}} \in F_{\mathfrak{u}}$ in the decomposition (1) are defined by the property that

$$
\begin{equation*}
f_{\mathfrak{u}}\left(\boldsymbol{x}_{\mathfrak{u}}\right)=0 \quad \text { if } \quad x_{j}=a \quad \text { and } \quad j \in \mathfrak{u} . \tag{21}
\end{equation*}
$$

For each fixed value of $a \in D$, the decomposition (1) satisfying this property is uniquely determined. (For a given finite subset $\mathfrak{v} \subset \mathbb{N}$, set $x_{j}=a$ for all $j \notin \mathfrak{v}$ in (1). The only surviving terms on the right-hand side are those $f_{\mathfrak{u}}$ for which $\mathfrak{u} \subseteq \mathfrak{v}$. Working from the smallest subsets upwards, one proves inductively that each $f_{\mathfrak{u}}$ is uniquely determined.) For this anchored decomposition we have

$$
f_{d}\left(x_{1}, \ldots, x_{d}\right):=\sum_{\mathfrak{u} \subseteq\{1, \ldots, d\}} f_{\mathfrak{u}}\left(\boldsymbol{x}_{\mathfrak{u}}\right)=f\left(x_{1}, \ldots, x_{d}, a, a, \ldots\right),
$$

which follows on setting $x_{j}=a$ for $j>d$ in the decomposition (1) and using the property (21).
Since there are an infinite number of choices for a, there are correspondingly an infinite number of decompositions, which are easily seen to be different. Under the conditions of Theorem 2 we know that each anchored decomposition will give the same value for the exact integral $\mathcal{I}(f)$, no matter the choice of the anchor a. However, the MDM developed below will in general give different approximate results for different anchors.

This choice of spaces $F_{\mathfrak{u}}$ also allows the so-called "ANOVA" decomposition (see e.g., [29]) and many other possibilities. For example, a decomposition could be determined as the result of some numerical computation.

Example 6 With the same definition of $F_{\mathfrak{u}}$ as in Example 5, we can express the zero function by the zero decomposition, where the uniform convergence holds true, and we obviously have $\mathcal{I}(0)=0$. We now present an example of a decomposition of the zero function which at face value gives a non-zero value for the integral.

For $k \geq 1$, let $\psi_{k}(t)=2^{k+1}\left(1-\left|2^{k+1} t-1\right|\right)_{+}$with $t \in D=\left[-\frac{1}{2}, \frac{1}{2}\right]$, i.e., $\psi_{k}(t)$ is the 'hat' function supported on $\left[0,2^{-k}\right]$ and satisfying $\int_{D} \psi_{k}(t) \mathrm{d} t=1$. For $\boldsymbol{x}=\left(x_{1}, x_{2}, x_{3}, \ldots\right) \in D^{\mathbb{N}}$, we choose

$$
f_{\{1\}}(\boldsymbol{x})=\psi_{1}\left(x_{1}\right), \quad \text { and } \quad f_{\{1, \ldots, k\}}(\boldsymbol{x})=\psi_{k}\left(x_{1}\right)-\psi_{k-1}\left(x_{1}\right) \quad \text { for } \quad k \geq 2
$$

and set $f_{\mathfrak{u}}=0$ for all other finite subsets $\mathfrak{u}$. We obviously have that $f_{\{1, \ldots, k\}} \in F_{\{1, \ldots, k\}}$ and the sum

$$
f_{d}\left(x_{1}, \ldots, x_{d}\right):=\sum_{\mathfrak{u} \subseteq\{1, \ldots, d\}} f_{\mathfrak{u}}(\boldsymbol{x})=\sum_{k=1}^{d} f_{\{1, \ldots, k\}}(\boldsymbol{x})=\psi_{d}\left(x_{1}\right)
$$

is pointwise, but not dominantly, convergent to zero for all $\boldsymbol{x} \in D^{\mathbb{N}}$. However,

$$
\sum_{\mathfrak{u} \subseteq\{1, \ldots, d\}} I_{\mathfrak{u}}\left(f_{\mathfrak{u}}\right)=\sum_{k=1}^{d} I_{\{1, \ldots, k\}}\left(f_{\{1, \ldots, k\}}\right)=1 \quad \forall d \geq 1
$$

This example shows that the dominated convergence of the decomposition in (10) is crucial.
As a final comment, we remark that it is often more convenient in practice to choose the spaces $F_{\mathfrak{u}}$ to be reproducing kernel spaces based on a simple univariate kernel, because the norms of a given function are typically smaller. In this case the decomposition in (1) is uniquely determined.

### 3.4 A strengthened assumption on $C_{\mathfrak{u}}$ and $B_{\mathfrak{u}}$

For our formal setting we make a stronger assumption than (18), namely we assume a certain decay

$$
\begin{equation*}
\alpha_{0}:=\operatorname{decay}\left(\left\{C_{\mathfrak{u}} B_{\mathfrak{u}}\right\}_{\mathfrak{u}}\right):=\sup \left\{\alpha: \sum_{|\mathfrak{u}|<\infty}\left(C_{\mathfrak{u}} B_{\mathfrak{u}}\right)^{1 / \alpha}<\infty\right\}>1 \tag{A4}
\end{equation*}
$$

The purpose of this strengthened assumption will become clear in Subsection 4.2, when we construct the active set.

### 3.5 Allowed algorithms

In general, the components $f_{\mathfrak{u}}$ in the decomposition $f=\sum_{|\mathfrak{u}|<\infty} f_{\mathfrak{u}}$ are not known explicitly. Nevertheless, it is assumed that we can sample $f_{\mathfrak{u}}$ at arbitrary points $\boldsymbol{x}_{\mathfrak{u}}$ in the domain. Explicitly, we make the following assumption.
(A5) For a finite set $\mathfrak{u} \subset \mathbb{N}$ we can evaluate $f_{\mathfrak{u}}\left(\boldsymbol{x}_{\mathfrak{u}}\right)$ for $\boldsymbol{x}_{\mathfrak{u}} \in D^{|\mathfrak{u}|}$ at cost $£(|\mathfrak{u}|)$, where $£$ is a given non-decreasing function.

At this point we make no assumption about our ability to evaluate $f(\boldsymbol{x})$, but we shall return to this question in Section 5 .

We assume that for each $\mathfrak{u}$ we have at our disposal a sequence $\left\{A_{\mathfrak{u}, n}\right\}_{n \in \mathbb{N} \cup\{0\}}$ of quadrature rules approximating $I_{\mathfrak{u}}\left(f_{\mathfrak{u}}\right)$ as in (8), with $A_{\mathfrak{u}, 0}=0$, and, moreover, the following condition is satisfied:
(A6) There exists $q>0$ with the following property: for each $\mathfrak{u}$, there exist $G_{\mathfrak{u}, q}>0$ such that the worst case error of $A_{\mathfrak{u}, n}$ in the unit ball of $F_{\mathfrak{u}}$ satisfies

$$
\begin{equation*}
\left\|I_{\mathfrak{u}}-A_{\mathfrak{u}, n}\right\|=\sup _{\left\|f_{\mathfrak{u}}\right\|_{F_{u}} \leq 1}\left|I_{\mathfrak{u}}\left(f_{\mathfrak{u}}\right)-A_{\mathfrak{u}, n}\left(f_{\mathfrak{u}}\right)\right| \leq \frac{G_{\mathfrak{u}, q}}{(n+1)^{q}} \quad \text { for } \quad n=0,1,2, \ldots \tag{22}
\end{equation*}
$$

Note that $q$ is not uniquely defined. Since (22) holds even for $n=0$, we can assume $C_{\mathfrak{u}} \leq G_{u, q}$ where $C_{\mathfrak{u}}$ is as in (17). We also observe that (22) implies $\lim _{n \rightarrow \infty}\left\|I_{\mathfrak{u}}-A_{\mathfrak{u}, n}\right\|=0$.

## 4 Multivariate Decomposition Method

We are now ready to introduce the Multivariate Decomposition Method (MDM) in our setting.

### 4.1 MDM

As in $[35,43,44]$, the first step of the method is to construct, for given $\varepsilon>0$, what we call here the active set $\mathcal{U}(\varepsilon)$ - a finite collection of those subsets $\mathfrak{u} \subset \mathbb{N}$ that are most important for the integration problem. Specifically, under our standing assumptions (A1)-(A6), we choose a set $\mathcal{U}(\varepsilon)$ such that

$$
\begin{equation*}
\sum_{\mathfrak{u} \notin \mathcal{U}(\varepsilon)}\left|I_{\mathfrak{u}}\left(f_{\mathfrak{u}}\right)\right| \leq \frac{\varepsilon}{2} . \tag{23}
\end{equation*}
$$

The $\operatorname{MDM} \mathcal{A}_{\varepsilon}(f)$ for the integral $\mathcal{I}(f)$ is then given by (8), with the values of $n_{\mathfrak{u}}$ chosen such that

$$
\begin{equation*}
\sum_{\mathfrak{u} \in \mathcal{U}(\varepsilon)}\left|I_{\mathfrak{u}}\left(f_{\mathfrak{u}}\right)-A_{\mathfrak{u}, n_{\mathfrak{u}}}\left(f_{\mathfrak{u}}\right)\right| \leq \frac{\varepsilon}{2} . \tag{24}
\end{equation*}
$$

It then follows that for all $f \in \mathcal{F}$ the integration error of MDM satisfies

$$
\left|\mathcal{I}(f)-\mathcal{A}_{\varepsilon}(f)\right| \leq \sum_{\mathfrak{u} \notin \mathcal{U}(\varepsilon)}\left|I_{\mathfrak{u}}\left(f_{\mathfrak{u}}\right)\right|+\sum_{\mathfrak{u} \in \mathcal{U}(\varepsilon)}\left|I_{\mathfrak{u}}\left(f_{\mathfrak{u}}\right)-A_{\mathfrak{u}, n_{\mathfrak{u}}}\left(f_{\mathfrak{u}}\right)\right| \leq \frac{\varepsilon}{2}+\frac{\varepsilon}{2}=\varepsilon .
$$

Consequently, the worst case error of $\mathcal{A}_{\varepsilon}$ in $\mathcal{F}$ satisfies

$$
e\left(\mathcal{A}_{\varepsilon} ; \mathcal{F}\right):=\sup _{f \in \mathcal{F}}\left|\mathcal{I}(f)-\mathcal{A}_{\varepsilon}(f)\right| \leq \varepsilon .
$$

The information cost is

$$
\begin{equation*}
\operatorname{cost}\left(\mathcal{A}_{\varepsilon}\right):=\sum_{\mathfrak{u} \in \mathcal{U}(\varepsilon)} n_{\mathfrak{u}} £(|\mathfrak{u}|) . \tag{25}
\end{equation*}
$$

We remark that such an active set $\mathcal{U}(\varepsilon)$ is not unique. Note the two distinct special cases $\mathcal{U}(\varepsilon)=\emptyset$ (which corresponds to $\mathcal{A}_{\varepsilon}=0$ ) and $\mathcal{U}(\varepsilon)=\{\emptyset\}$ (which corresponds to $\mathcal{A}_{\varepsilon}(f)=f_{\emptyset}$ ).

### 4.2 Constructing $\mathcal{U}(\varepsilon)$

We use essentially the same approach for constructing the active set $\mathcal{U}(\varepsilon)$ as in [43]. Recall that for each $\mathfrak{u}$ we have $\left|I_{\mathfrak{u}}\left(f_{\mathfrak{u}}\right)\right| \leq C_{\mathfrak{u}} B_{\mathfrak{u}}$, and that the sequence $\left\{C_{\mathfrak{u}} B_{\mathfrak{u}}\right\}$ satisfies (A4). It follows that for any $\alpha \in\left(1, \alpha_{0}\right)$ we may define

$$
\begin{equation*}
\mathcal{U}(\varepsilon)=\mathcal{U}(\varepsilon, \alpha):=\left\{\mathfrak{u}:\left(C_{\mathfrak{u}} B_{\mathfrak{u}}\right)^{1-1 / \alpha}>\frac{\varepsilon / 2}{\sum_{|\mathfrak{v}|<\infty}\left(C_{\mathfrak{v}} B_{\mathfrak{v}}\right)^{1 / \alpha}}\right\}, \tag{26}
\end{equation*}
$$

and this would yield (23). Moreover, following the proof of [43, Theorem 2] we can obtain an upper bound on the size of the resulting active set, as given in the proposition below.

Proposition 7 Let $\mathcal{U}(\varepsilon, \alpha)$ be given by (26). Then for any $\varepsilon>0$ and $\alpha \in\left(1, \alpha_{0}\right)$ we have

$$
|\mathcal{U}(\varepsilon, \alpha)|<\left(\frac{2}{\varepsilon}\right)^{\frac{1}{\alpha-1}}\left(\sum_{|\mathfrak{u}|<\infty}\left(C_{\mathfrak{u}} B_{\mathfrak{u}}\right)^{\frac{1}{\alpha}}\right)^{\frac{\alpha}{\alpha-1}} .
$$

### 4.3 Constructing $A_{u, n_{u}}\left(f_{\mathfrak{u}}\right)$

The main difficulty in the construction of the algorithms $A_{\mathfrak{u}, n_{\mathfrak{u}}}$ for $\mathfrak{u} \in \mathcal{U}(\varepsilon, \alpha)$ is the selection of the numbers $n_{\mathfrak{u}}$. A natural approach is to minimize the information cost (25) subject to the desired error bound (24) being attained. This depends on the rate of convergence of the worst case errors $\left\|I_{\mathfrak{u}}-A_{\mathfrak{u}, n}\right\|$ for fixed $\mathfrak{u}$ and $n \rightarrow \infty$. For a given selection of the $n_{\mathfrak{u}}$ this rate is determined by (22), from which it follows that for any $f \in \mathcal{F}$ we have

$$
\begin{equation*}
\sum_{\mathfrak{u} \in \mathcal{U}(\varepsilon, \alpha)}\left|I_{\mathfrak{u}}(f)-A_{\mathfrak{u}, n_{\mathfrak{u}}}(f)\right| \leq \sum_{\mathfrak{u} \in \mathcal{U}(\varepsilon, \alpha)} \frac{G_{\mathfrak{u}, q} B_{\mathfrak{u}}}{\left(n_{\mathfrak{u}}+1\right)^{q}} . \tag{27}
\end{equation*}
$$

Observe that if we take

$$
n_{\mathfrak{u}}=n_{\mathfrak{u}}(\varepsilon, q)=\left\lfloor h_{\mathfrak{u}}\right\rfloor,
$$

where the positive real numbers $h_{\mathfrak{u}}$ minimize $\sum_{\mathfrak{u} \in \mathcal{U}(\varepsilon, \alpha)} h_{\mathfrak{u}} £(|\mathfrak{u}|)$ subject to $\sum_{\mathfrak{u} \in \mathcal{U}(\varepsilon, \alpha)} G_{\mathfrak{u}, q} B_{\mathfrak{u}} / h_{\mathfrak{u}}^{q}=\varepsilon / 2$, then both the error and the information cost are controlled, since

$$
\sum_{\mathfrak{u} \in \mathcal{U}(\varepsilon, \alpha)} \frac{G_{\mathfrak{u}, q} B_{\mathfrak{u}}}{\left(n_{\mathfrak{u}}+1\right)^{q}} \leq \sum_{\mathfrak{u} \in \mathcal{U}(\varepsilon, \alpha)} \frac{G_{\mathfrak{u}, q} B_{\mathfrak{u}}}{h_{\mathfrak{u}}^{q}}=\frac{\varepsilon}{2} \quad \text { and } \quad \sum_{\mathfrak{u} \in \mathcal{U}(\varepsilon, \alpha)} n_{\mathfrak{u}} £(|\mathfrak{u}|) \leq \sum_{\mathfrak{u} \in \mathcal{U}(\varepsilon, \alpha)} h_{\mathfrak{u}} £(|\mathfrak{u}|) .
$$

An explicit formula for such $h_{\mathfrak{u}}$ can be obtained using a Lagrange multiplier argument, giving

$$
\begin{equation*}
h_{\mathfrak{u}}=\left(\frac{2}{\varepsilon} \sum_{\mathfrak{v} \in \mathcal{U}(\varepsilon, \alpha)} £(|\mathfrak{v}|)^{q /(q+1)}\left(G_{\mathfrak{v}, q} B_{\mathfrak{v}}\right)^{1 /(q+1)}\right)^{1 / q}\left(\frac{G_{\mathfrak{u}, q} B_{\mathfrak{u}}}{£(|\mathfrak{u}|)}\right)^{1 /(q+1)} . \tag{28}
\end{equation*}
$$

This analysis leads to the following theorem.
Theorem 8 Under the standing assumptions (A1)-(A6), for any $\varepsilon>0$ and $\alpha \in\left(1, \alpha_{0}\right)$ the algorithm $\mathcal{A}_{\varepsilon}$ with $\mathcal{U}(\varepsilon)=\mathcal{U}(\varepsilon, \alpha)$ defined by (26) and $n_{\mathfrak{u}}=\left\lfloor h_{\mathfrak{u}}\right\rfloor$ with $h_{\mathfrak{u}}$ defined by (28) produces an approximation to the integral $\mathcal{I}$ with worst case error $e\left(\mathcal{A}_{\varepsilon} ; \mathcal{F}\right) \leq \varepsilon$ and

$$
\begin{align*}
\operatorname{cost}\left(\mathcal{A}_{\varepsilon}\right) \leq \sum_{\mathfrak{u} \in \mathcal{U}(\varepsilon, \alpha)} h_{\mathfrak{u}} £(|\mathfrak{u}|) & \leq\left(\frac{2}{\varepsilon}\right)^{1 / q}\left(\sum_{\mathfrak{u} \in \mathcal{U}(\varepsilon, \alpha)} £(|\mathfrak{u}|)^{q /(q+1)}\left(G_{\mathfrak{u}, q} B_{\mathfrak{u}}\right)^{1 /(q+1)}\right)^{1+1 / q} \\
& \leq\left(\frac{2}{\varepsilon}\right)^{1 / \boldsymbol{q}}\left(\sum_{\mathfrak{u} \in \mathcal{U}(\varepsilon, \alpha)}\left(G_{\mathfrak{u}, q} B_{\mathfrak{u}}\right)^{1 /(q+1)}\right)^{1+1 / q} \max _{\mathfrak{u} \in \mathcal{U}(\varepsilon, \alpha)} £(|\mathfrak{u}|) . \tag{29}
\end{align*}
$$

If we wish, we could also assume, analogously to Assumption (A4), that

$$
\alpha_{q}:=\operatorname{decay}\left(\left\{G_{\mathfrak{u}, q} B_{\mathfrak{u}}\right\}_{\mathfrak{u}}\right):=\sup \left\{\tau: \sum_{|\mathfrak{u}|<\infty}\left(G_{\mathfrak{u}, q} B_{\mathfrak{u}}\right)^{1 / \tau}<\infty\right\}>1 .
$$

In that case, if it also happens that $q<\alpha_{q}-1$, then the sum in (29) would be uniformly bounded for all $\varepsilon>0$,

$$
\sum_{\mathfrak{u} \in \mathcal{U}(\varepsilon, \alpha)}\left(G_{\mathfrak{u}, q} B_{\mathfrak{u}}\right)^{1 /(q+1)} \leq \sum_{|\mathfrak{u}|<\infty}\left(G_{\mathfrak{u}, q} B_{\mathfrak{u}}\right)^{1 /(q+1)}<\infty .
$$

Then, up to a constant, the cost in Theorem 8 would be upper bounded by $\varepsilon^{-1 / q} \max _{u \in \mathcal{U}(\varepsilon, \alpha)} £(|\mathfrak{u}|)$.
Theorem 8 differs from [43, Theorem 9] in the following way: the assumed bound on the errors for the corresponding algorithms $A_{\mathfrak{u}, n_{\mathfrak{u}}}$ in [43, Formula (18)] involve also some logarithmic factors in $n_{\mathfrak{u}}$ which results in an overall error that is bounded by $\varepsilon$ times a small factor depending on $\varepsilon$. Later in Subsection 5.6 we will also encounter such a scenario, and we will relax the requirement (24) a little by neglecting those multiplicative factors when choosing $n_{\mathfrak{u}}$. In this way we obtain an algorithm $\overline{\mathcal{A}}_{\varepsilon}$ whose error is slightly larger than $\varepsilon$.

Remark 9 For a practical implementation we note that the construction of the active set $\mathcal{U}(\varepsilon)=$ $\mathcal{U}(\varepsilon, \alpha)$ in (26) depends on the error request $\varepsilon$ and the choice of the decomposition through the spaces $F_{\mathfrak{u}}$ and hence on values of $C_{\mathfrak{u}}$ and $B_{\mathfrak{u}}$, and additionally on the choice of the parameter $\alpha$. Moreover, the infinite sum from the denominator in (26) needs to be estimated from above. The values of $q$ and $G_{\mathfrak{u}, q}$ in (22) depend on the available algorithms $A_{\mathfrak{u}, n_{\mathfrak{u}}}$ and enter the formula for $n_{\mathfrak{u}}$ via (28).

## 5 First application: anchored RKHS

In both this and the next sections, the space $F_{\mathfrak{u}}$ is an anchored space, anchored at 0 . This means that for $\mathfrak{u} \neq \emptyset$, every function $f_{\mathfrak{u}} \in F_{\mathfrak{u}}$ satisfies (21) with $a=0$, and that if $\mathfrak{u} \neq \mathfrak{v}$ then $F_{\mathfrak{u}} \cap F_{\mathfrak{v}}$ contains only the zero function. In Subsection 5.1 we state an explicit formula for the anchored decomposition to demonstrate how (A5) holds.

In Subsection 5.2, we define the setting for the case of a general anchored reproducing kernel and a general domain $D$. In Subsection 5.3 we specialize the integration domain to $\left[-\frac{1}{2}, \frac{1}{2}\right]$ and the kernel to one that leads to a subspace of the space described in Subsection 3.3, with a redefined (but equivalent) norm. In Subsection 5.4 we consider again the motivating example from (20). In Subsection 5.5 we specialize the quadrature formulas to lattice rules. Then, in Subsection 5.6 we specialize the quadrature formulas to Smolyak's quadrature, and finally develop the algorithm $\overline{\mathcal{A}}_{\varepsilon}$.

### 5.1 Anchored decomposition and (A5)

Recall that (A5) is about the cost of evaluating individual terms $f_{\mathfrak{u}}$ from $f=\sum_{|\mathfrak{u}|<\infty} f_{\mathfrak{u}}$. It is shown in [29] that, for the anchored decomposition with anchor at 0 , the value of $f_{\mathfrak{u}}\left(\boldsymbol{x}_{\mathfrak{u}}\right)$ can be expressed as a combination of at most $2^{|u|}$ values of $f$, specifically

$$
f_{\mathfrak{u}}\left(\boldsymbol{x}_{\mathfrak{u}}\right)=\sum_{\mathfrak{v} \subseteq \mathfrak{u}}(-1)^{|\mathfrak{u}|-|\mathfrak{v}|} f\left(\boldsymbol{x}_{\mathfrak{v}} ; \mathbf{0}\right),
$$

where $f\left(\boldsymbol{x}_{\mathfrak{v}} ; \mathbf{0}\right)$ indicates that we evaluate $f(\boldsymbol{x})$ with $x_{j}$ set to 0 for $j \notin \mathfrak{v}$. Here we assume as in, e.g., [28], that we can sample $f(\boldsymbol{x})$ at some cost provided that $\boldsymbol{x}$ has only finitely many $x_{j}$ different from 0. More precisely, we suppose that we can evaluate $f\left(\boldsymbol{x}_{u} ; \mathbf{0}\right)$ at the cost $\$(|\mathfrak{u}|)$, where $\$$ : $\{0,1,2, \ldots\} \rightarrow(0, \infty)$ is a given non-decreasing cost function. It follows that $f_{\mathfrak{u}}\left(\boldsymbol{x}_{\mathfrak{u}}\right)$ can be obtained at a cost of

$$
\begin{equation*}
\mathscr{L}(|\mathfrak{u}|)=\sum_{k=0}^{|\mathfrak{u}|}\binom{|\mathfrak{u}|}{k} \$(k) \leq 2^{|\mathfrak{u}|} \$(|\mathfrak{u}|) . \tag{30}
\end{equation*}
$$

### 5.2 The anchored RKHS setting

Let $F=H(K)$ be a reproducing kernel Hilbert space of univariate functions with the kernel $K$ : $D \times D \rightarrow \mathbb{R}$. We assume that $K$ has an anchor $0 \in D$, i.e., $K(0,0)=0$. For $g \in F$, it follows from the reproducing property $g(x)=\langle g, K(x, \cdot)\rangle_{F}$ that $|g(0)| \leq\|g\|_{F}\|K(0, \cdot)\|_{F}=\|g\|_{F} \sqrt{K(0,0)}=0$, implying $g(0)=0$ and, as a special case, $K(x, 0)=0$ for all $x \in D$.

For nonempty $\mathfrak{u}$, the space $F_{\mathfrak{u}}$ is defined to be the reproducing kernel Hilbert space with kernel

$$
\begin{equation*}
K_{\mathfrak{u}}\left(\boldsymbol{x}_{\mathfrak{u}}, \boldsymbol{y}_{\mathfrak{u}}\right)=\prod_{j \in \mathfrak{u}} K\left(x_{j}, y_{j}\right) . \tag{31}
\end{equation*}
$$

That is, $F_{\mathfrak{u}}=H\left(K_{\mathfrak{u}}\right)$ is the $|\mathfrak{u}|$-fold tensor product of the space $F$ and consists of functions whose variables are those listed in $\mathfrak{u}$.

In the space $F_{\mathfrak{u}}$ so defined, point evaluation is a continuous linear functional: indeed for $\boldsymbol{x}_{\mathfrak{u}} \in$ $D^{\mathfrak{u}}$ and $g_{\mathfrak{u}} \in F_{\mathfrak{u}}$ we have $g_{\mathfrak{u}}\left(\boldsymbol{x}_{\mathfrak{u}}\right)=\left\langle g_{\mathfrak{u}}, K_{\mathfrak{u}}\left(\boldsymbol{x}_{\mathfrak{u}}, \cdot\right)\right\rangle_{F_{\mathfrak{u}}}$, and hence $\left|g_{\mathfrak{u}}\left(\boldsymbol{x}_{\mathfrak{u}}\right)\right| \leq\left\|g_{\mathfrak{u}}\right\|_{F_{\mathfrak{u}}}\left\|K_{\mathfrak{u}}\left(\boldsymbol{x}_{\mathfrak{u}}, \cdot\right)\right\|_{F_{\mathfrak{u}}}=$ $\left\|g_{\mathfrak{u}}\right\|_{F_{\mathfrak{u}}}\left(K_{\mathfrak{u}}\left(\boldsymbol{x}_{\mathfrak{u}}, \boldsymbol{x}_{\mathfrak{u}}\right)\right)^{1 / 2}$, from which it is easily seen that the norm of the point evaluation functional is

$$
\sup _{\left\|g_{\mathfrak{u}}\right\|_{F_{\mathfrak{u}} \leq 1} \leq 1}\left|g_{\mathfrak{u}}\left(\boldsymbol{x}_{\mathfrak{u}}\right)\right|=\left(K_{\mathfrak{u}}\left(\boldsymbol{x}_{\mathfrak{u}}, \boldsymbol{x}_{\mathfrak{u}}\right)\right)^{1 / 2}=\left(\prod_{j \in \mathfrak{u}} K\left(x_{j}, x_{j}\right)\right)^{1 / 2} .
$$

We may now define $\mathcal{F}$ to be the class of functions

$$
\begin{equation*}
f(\boldsymbol{x})=\sum_{|\mathfrak{u}|<\infty} f_{\mathfrak{u}}\left(\boldsymbol{x}_{\mathfrak{u}}\right) \quad \text { with } \quad f_{\mathfrak{u}} \in F_{\mathfrak{u}} \quad \text { and } \quad\left\|f_{\mathfrak{u}}\right\|_{F_{\mathfrak{u}}} \leq B_{\mathfrak{u}} \tag{32}
\end{equation*}
$$

and such that the above series is uniformly convergent for all $\boldsymbol{x} \in D^{\mathbb{N}}$. The class $\mathcal{F}$ can be relatively large when the kernel $K$ is bounded. Suppose that $\|K\|_{\infty}:=\sup _{x \in D} K(x, x)<\infty$. Then it follows from the reproducing property of $K_{\mathfrak{u}}$ and from (4) that the terms in the decomposition (1) satisfy

$$
\sum_{|\mathfrak{u}|<\infty}\left|f_{\mathfrak{u}}\left(\boldsymbol{x}_{\mathfrak{u}}\right)\right|=\sum_{|\mathfrak{u}|<\infty}\left|\left\langle f_{\mathfrak{u}}, K_{\mathfrak{u}}\left(\boldsymbol{x}_{\mathfrak{u}}, \cdot\right)\right\rangle_{F_{\mathfrak{u}}}\right| \leq \sum_{|\mathfrak{u}|<\infty}\left\|f_{\mathfrak{u}}\right\|_{F_{\mathfrak{u}}}\left(K_{\mathfrak{u}}\left(\boldsymbol{x}_{\mathfrak{u}}, \boldsymbol{x}_{\mathfrak{u}}\right)\right)^{1 / 2} \leq \sum_{|\mathfrak{u}|<\infty} B_{\mathfrak{u}}\|K\|_{\infty}^{|\mathfrak{u}| / 2} .
$$

Hence, if $\sum_{|\mathfrak{u}|<\infty} B_{\mathfrak{u}}\|K\|_{\infty}^{\mid \mathfrak{u} / 2}<\infty$ then the convergence in (1) is automatically uniform, and we may define $\mathcal{F}$ as the class of functions (32) without further restriction. On the other hand, if the kernel $K$ is unbounded then $\|K\|_{\infty}=\infty$, and the class $\mathcal{F}$ would be more restrictive in order to guarantee that point evaluation is bounded. An example of such an unbounded kernel on $D$ is provided by

$$
D=\mathbb{R} \quad \text { and } \quad K(x, y)=\frac{|x|+|y|-|x-y|}{2} .
$$

### 5.3 Specializing the kernel

We now apply our results to a special case of the reproducing kernel Hilbert space setting. We let

$$
\begin{equation*}
D=\left[-\frac{1}{2}, \frac{1}{2}\right], \quad \rho(x)=1, \quad K(x, y)=\frac{|x|+|y|-|x-y|}{2} \tag{33}
\end{equation*}
$$

and take $F=H(K)$ to be the corresponding reproducing kernel Hilbert space. Since $K(0,0)=0$, this is clearly an anchored space with the anchor 0 . Moreover, it can easily be verified that the corresponding norm is given by

$$
\|g\|_{F}^{2}=\int_{-1 / 2}^{1 / 2}\left|g^{\prime}(x)\right|^{2} \mathrm{~d} x
$$

For nonempty $\mathfrak{u}$ with $|\mathfrak{u}|<\infty$, let $F_{\mathfrak{u}}=H\left(K_{\mathfrak{u}}\right)$ with kernel (31). Then the norm in the space $F_{\mathfrak{u}}$ is given by

$$
\left\|g_{\mathfrak{u}}\right\|_{F_{\mathfrak{u}}}^{2}=\int_{\left[-\frac{1}{2}, \frac{1}{2}\right]}\left|\frac{\partial^{|\mathfrak{u}|}}{} \frac{\boldsymbol{x}_{\mathfrak{u}}}{} g_{\mathfrak{u}}\left(\boldsymbol{x}_{\mathfrak{u}}\right)\right|^{2} \mathrm{~d} \boldsymbol{x}_{\mathfrak{u}} \quad \text { for any } g_{\mathfrak{u}} \in F_{\mathfrak{u}}
$$

where $\partial^{|\mathfrak{u}|} / \partial \boldsymbol{x}_{\mathfrak{u}}=\prod_{j \in \mathfrak{u}}\left(\partial / \partial x_{j}\right)$. For a function $f \in \mathcal{F}$ with anchored decomposition $f=\sum_{|\mathfrak{u}|<\infty} f_{\mathfrak{u}}$, we now have

$$
\begin{equation*}
\int_{\left[-\frac{1}{2}, \frac{1}{2}\right]^{|\mathfrak{u}|}}\left|\frac{\partial^{|\mathfrak{u}|}}{\partial \boldsymbol{x}_{\mathfrak{u}}} f\left(\boldsymbol{x}_{\mathfrak{u}} ; \mathbf{0}\right)\right|^{2} \mathrm{~d} \boldsymbol{x}_{\mathfrak{u}}=\left\|f_{\mathfrak{u}}\right\|_{F_{\mathfrak{u}}}^{2} \tag{34}
\end{equation*}
$$

which follows from $f\left(\boldsymbol{x}_{\mathfrak{u}} ; \mathbf{0}\right)=\sum_{\mathfrak{v} \subseteq \mathfrak{u}} f_{\mathfrak{v}}\left(\boldsymbol{x}_{\mathfrak{v}}\right)$ together with $\partial^{|\mathfrak{u}|} f_{\mathfrak{v}} / \partial \boldsymbol{x}_{\mathfrak{u}}=0$ if $\mathfrak{v}$ is a proper subset of $\mathfrak{u}$.
For univariate integration $I(g)=\int_{-1 / 2}^{1 / 2} g(x) \mathrm{d} x$ with $g \in F=H(K)$, it is easy to verify that $c_{0}:=\|I\|_{F}=12^{-1 / 2}$. Due to the tensor product structure of $F_{\mathfrak{u}}$, we have from (17) that

$$
\begin{equation*}
C_{\mathfrak{u}}=\left\|I_{\mathfrak{u}}\right\|=c_{0}^{|\mathfrak{u}|}=12^{-|\mathfrak{u}| / 2} \tag{35}
\end{equation*}
$$

### 5.4 Examples of integration problems

Consider again the example in (20), but now with the more convenient choice $F_{\mathfrak{u}}=H\left(K_{\mathfrak{u}}\right)$. For $\mathfrak{u} \subset \mathbb{N}$, we then have

$$
\begin{equation*}
f\left(\boldsymbol{x}_{\mathfrak{u}} ; \mathbf{0}\right)=\frac{1}{1+\sum_{j \in \mathfrak{u}} x_{j} / j^{2}} \quad \text { and } \quad \frac{\partial^{|\mathfrak{u}|}}{\partial \boldsymbol{x}_{\mathfrak{u}}} f\left(\boldsymbol{x}_{\mathfrak{u}} ; \mathbf{0}\right)=\frac{(-1)^{|\mathfrak{u}|}|\mathfrak{u}|!}{\left(\prod_{j \in \mathfrak{u}} j^{2}\right)\left(1+\sum_{j \in \mathfrak{u}} x_{j} / j^{2}\right)^{|\mathfrak{u}|+1}}, \tag{36}
\end{equation*}
$$

and hence from (34), together with $x_{j} \geq-1 / 2$ and $\sum_{j=1}^{\infty} 1 / j^{2}=\pi^{2} / 6$,

$$
\left\|f_{\mathfrak{u}}\right\|_{F_{\mathfrak{u}}} \leq\left(1-\frac{\pi^{2}}{12}\right)^{-1-|\mathfrak{u}|}|\mathfrak{u}|!\prod_{j \in \mathfrak{u}} j^{-2}=: B_{\mathfrak{u}}
$$

When combined with $\|K\|_{\infty}=1 / 2$ and (35), this gives

$$
\|K\|_{\infty}^{|\mathfrak{u}| / 2} B_{\mathfrak{u}}=2^{-|\mathfrak{u}| / 2}\left(1-\frac{\pi^{2}}{12}\right)^{-1-|\mathfrak{u}|}|\mathfrak{u}|!\prod_{j \in \mathfrak{u}} j^{-2} \quad \text { and } \quad C_{\mathfrak{u}} B_{\mathfrak{u}}=12^{-|\mathfrak{u}| / 2}\left(1-\frac{\pi^{2}}{12}\right)^{-1-|\mathfrak{u}|}|\mathfrak{u}|!\prod_{j \in \mathfrak{u}} j^{-2}
$$

It follows from the lemma below that $\sum_{|\mathfrak{u}|<\infty}\|K\|_{\infty}^{|\mathfrak{u}| / 2} B_{\mathfrak{u}}<\infty$ (and hence the convergence in (1) is uniform), and that $\alpha_{0}$ in $(\mathbf{A 4})$ is given by $\alpha_{0}=\operatorname{decay}\left(\left\{C_{\mathfrak{u}} B_{\mathfrak{u}}\right\}_{\mathfrak{u}}\right)=2$.

Lemma 10 Let $b_{1} \geq 0$. Suppose the sequence $\left\{g_{j}\right\}_{j \geq 1}$ with $g_{j}>0$ has

$$
\operatorname{decay}\left(\left\{g_{j}\right\}_{j \geq 1}\right):=\sup \left\{\tau: \sum_{j=1}^{\infty} g_{j}^{1 / \tau}<\infty\right\}=: b_{2}>\max \left(b_{1}, 0\right)
$$

Then

$$
\operatorname{decay}\left(\left\{(|\mathfrak{u}|!)^{b_{1}} \prod_{j \in \mathfrak{u}} g_{j}\right\}_{\mathfrak{u}}\right)=b_{2}
$$

Proof. This is a special case of [7, Theorem 5]. Here we provide a simple proof. For any $\tau \in\left(b_{1}, b_{2}\right)$,

$$
\sum_{|\mathfrak{u}|<\infty}(|\mathfrak{u}|!)^{b_{1} / \tau} \prod_{j \in \mathfrak{u}} g_{j}^{1 / \tau}=\sum_{\ell=0}^{\infty}(\ell!)^{b_{1} / \tau} \sum_{|\mathfrak{u}|=\ell} \prod_{j \in \mathfrak{u}} g_{j}^{1 / \tau} \leq \sum_{\ell=0}^{\infty}(\ell!)^{b_{1} / \tau-1}\left(\sum_{j=1}^{\infty} g_{j}^{1 / \tau}\right)^{\ell}<\infty
$$

where the first inequality follows from $\left(\sum_{j=1}^{\infty} a_{j}\right)^{\ell} \geq \ell!\sum_{|\mathfrak{u}|=\ell} \prod_{j \in \mathfrak{u}} a_{j}$, and in the last expression the finiteness of the sum over $j$ follows from $\tau<b_{2}$, and the finiteness of the sum over $\ell$ follows from the ratio test using $\tau>b_{1}$.

This example motivates us to consider in the rest of this section the case in which (A2) holds with

$$
\begin{equation*}
B_{\mathfrak{u}}=(|\mathfrak{u}|!)^{b_{1}} \mu \prod_{j \in \mathfrak{u}}(\kappa j)^{-b_{2}} \quad \text { for some } \quad b_{2}>\max \left(b_{1}, 0\right) \quad \text { and some } \quad \mu, \kappa>0 \tag{37}
\end{equation*}
$$

The lemma with (35) then gives

$$
\alpha_{0}=\operatorname{decay}\left(\left\{C_{\mathfrak{u}} B_{\mathfrak{u}}\right\}_{\mathfrak{u}}\right)=b_{2} .
$$

It is easy to verify the following proposition, see [34].
Proposition 11 For $C_{\mathfrak{u}}=12^{-|\mathfrak{u}| / 2}$ and $B_{\mathfrak{u}}$ satisfying (37), for $\mathcal{U}(\varepsilon, \alpha)$ defined by (26) with $\varepsilon>0$ and $\alpha \in\left(1, b_{2}\right)$, we have

$$
d(\varepsilon):=\max _{\mathfrak{u} \in \mathcal{U}(\varepsilon, \alpha)}|\mathfrak{u}|=O\left(\frac{\ln (1 / \varepsilon)}{\ln (\ln (1 / \varepsilon))}\right) \quad \text { as } \quad \varepsilon \rightarrow 0
$$

If $£(d)=\mathrm{e}^{O(d)}$ as $d \rightarrow \infty$, then the cost of evaluating $f_{\mathfrak{u}}\left(\boldsymbol{x}_{\mathfrak{u}}\right)$ for $\mathfrak{u} \in \mathcal{U}(\varepsilon, \alpha)$ is

$$
£(d(\varepsilon))=(1 / \varepsilon)^{O(1 / \ln (\ln (1 / \varepsilon)))} \quad \text { as } \quad \varepsilon \rightarrow 0 .
$$

We end this subsection with the following two remarks.
Remark 12 Suppose that evaluation of $f([\boldsymbol{x} ; \mathfrak{u}])$ incurs exponentially large cost $\$(|\mathfrak{u}|)=\mathrm{e}^{O(|\mathfrak{u}|)}$. Then it follows from (30) that the cost $£(|\mathfrak{u}|)$ of obtaining $f_{\mathfrak{u}}\left(\boldsymbol{x}_{\mathfrak{u}}\right)$ for $u \in \mathcal{U}(\varepsilon, \alpha)$ is still of order $\mathrm{e}^{O(|\mathfrak{u}|)}$, and hence, by Proposition 11, the cost is only

$$
(1 / \varepsilon)^{O(1 / \ln (\ln (1 / \varepsilon)))}
$$

Remark 13 Although Proposition 11 limits very efficiently the cardinality of the largest subset in the active set, Proposition 7 suggests that the cardinality of the active set itself is still polynomial in $1 / \varepsilon$. In particular, the active set may contain $\{1\}, \ldots,\{j\}$ for a large value of $j$. For the example in (20) we can use the following argument to limit the size of the largest label $j$ that needs to be considered. This is achieved by estimating the truncation error more accurately for the specific example, rather than by applying bounds on the worst case error.

For this example, it follows from (20) and (36) together with Taylor's theorem (expanding the univariate function $1 /(a+y)$ about $y=0$, with $a=1+\sum_{j \in \mathfrak{u}} x_{j} / j^{2}$ and $\left.y=\sum_{j \notin \mathfrak{u}} x_{j} / j^{2}\right)$ that

$$
f(\boldsymbol{x})-f\left(\boldsymbol{x}_{\mathfrak{u}} ; \mathbf{0}\right)=-\frac{1}{\left(1+\sum_{j \in \mathfrak{u}} \frac{x_{j}}{j^{2}}\right)^{2}} \sum_{j \notin \mathfrak{u}} \frac{x_{j}}{j^{2}}+\frac{1}{(1+\zeta(\boldsymbol{x}, \mathfrak{u}))^{3}}\left(\sum_{j \notin \mathfrak{u}} \frac{x_{j}}{j^{2}}\right)^{2}
$$

for some $\zeta(\boldsymbol{x}, \mathfrak{u}) \in\left(-\frac{\pi^{2}}{12}, \frac{\pi^{2}}{12}\right)$. Since the integral of the first term vanishes, we have

$$
\mathcal{I}[f(\cdot)-f(\cdot \mathfrak{u} ; \mathbf{0})] \leq \frac{1}{\left(1-\frac{\pi^{2}}{12}\right)^{3}} \int_{\left[-\frac{1}{2}, \frac{1}{2}\right]^{\mathbb{N}}}\left(\sum_{j \notin \mathfrak{u}} \frac{x_{j}}{j^{2}}\right)^{2} \mathrm{~d} \boldsymbol{x}=\frac{1}{12\left(1-\frac{\pi^{2}}{12}\right)^{3}} \sum_{j \notin \mathfrak{u}} \frac{1}{j^{4}}
$$

In particular, if we choose $\mathfrak{u}=\{1: \ell\}:=\{1,2, \ldots, \ell\}$ then we have

$$
\mathcal{I}[f(\cdot)-f(\cdot\{1: \ell\} ; \mathbf{0})] \leq \frac{1}{36\left(1-\frac{\pi^{2}}{12}\right)^{3}} \ell^{-3}
$$

We now take $\ell=\ell_{\varepsilon}$ so that the right hand side is less than $\varepsilon / 3$, implying $\ell=\ell_{\varepsilon}=\Omega\left(\varepsilon^{-1 / 3}\right)$. Then we replace the sum $\sum_{|\mathfrak{v}|<\infty}\left(C_{\mathfrak{v}} B_{\mathfrak{v}}\right)^{1 / \alpha}$ in (26) by $\sum_{\mathfrak{v} \in\{1: \ell\}}\left(C_{\mathfrak{v}} B_{\mathfrak{v}}\right)^{1 / \alpha}$, replace (23) by

$$
\sum_{\mathfrak{u} \in\{1: \ell\} \backslash \mathcal{U}(\varepsilon)}\left|I_{\mathfrak{u}}\left(f_{\mathfrak{u}}\right)\right| \leq \frac{\varepsilon}{3},
$$

and replace $\varepsilon / 2$ in (24) by $\varepsilon / 3$. Then MDM can be run as usual, and will still give an error bounded by $\varepsilon$, but with the simplification that subsets containing numbers bigger than $\ell_{\varepsilon}$ need never be considered. In effect, for this example the problem can be considered as an $\ell_{\varepsilon}$-dimensional problem, rather than as an infinite-dimensional one.

### 5.5 Specializing the quadrature to lattice rules

It can be shown by an adaptation of known results (see, e.g., [10, Theorem 5.9]) that in the case of the kernel in Subsection 5.3 we can construct shifted lattice rules with $n$ points in $|\mathfrak{u}|$ dimensions, where $n \geq 3$ is prime, such that (22) holds for all $q \in[1 / 2,1$ ), with

$$
G_{\mathfrak{u}, q}=2^{q}\left(\frac{2 \zeta(1 / q)}{\left(2 \pi^{2}\right)^{1 /(2 q)}}+12^{-1 /(2 q)}\right)^{|\mathfrak{u}| q}
$$

where $\zeta(x)=\sum_{k=1}^{\infty} k^{-x}$ is the Riemann zeta function. More precisely, the above result is adapted from known results for lattice rules by setting the weight $\gamma_{u}$ for the particular $\mathfrak{u}$ to be 1 and all other weights to be 0 . We follow the analysis of Subsection 4.3, but instead of taking $n_{\mathfrak{u}}=\left\lfloor h_{\mathfrak{u}}\right\rfloor$ we take $n_{\mathfrak{u}}$ to be the largest prime number such that $3 \leq n_{\mathfrak{u}} \leq h_{\mathfrak{u}}$, or set $n_{\mathfrak{u}}=0$ if this is not achievable. The remaining analysis in that subsection then applies.

More precisely, a shifted lattice rule with $n$ points for a $d$-variate function $g$ defined over $[-1 / 2,1 / 2]^{d}$ takes the form

$$
\frac{1}{n} \sum_{i=1}^{n} g\left(\left\{\frac{i \boldsymbol{z}}{n}+\boldsymbol{\Delta}\right\}-\frac{1}{2}\right)
$$

where $\boldsymbol{z} \in \mathbb{Z}^{d}$ is the generating vector and $\boldsymbol{\Delta} \in[0,1]^{d}$ is the shift. The braces around a vector indicate that we take the fractional part of each component in the vector, and the subtraction by $1 / 2$ from all components takes care of the translation from the standard unit cube $[0,1]^{d}$ to $[-1 / 2,1 / 2]^{d}$. A good generating vector for the lattice rule can be constructed using the fast component-by-component algorithm, see e.g., [33]. The shift can be generated randomly from the uniform distribution on $[0,1]^{d}$ (in this case the error bound holds in the root mean square sense), or the shift can be generated repeatedly until the desired error bound is achieved (in this case the error bound holds deterministically but the result is not fully constructive). See, e.g., [10] for details.

### 5.6 Specializing the quadrature to Smolyak's method

We now apply Smolyak's [39] quadrature scheme to the MDM in the RKHS context of this section, with kernel (33). Smolyak's construction is often used for tensor-product problems. It is built from a single family of univariate quadrature rules, and for every space $F_{\mathfrak{u}}$ of a given dimensionality $d=|\mathfrak{u}|$ we use the same family of rules. In the following we take the univariate quadrature rules to be trapezoidal rules since in this setting they achieve the optimal convergence rate of order 1.

For $d \geq 1$, Smolyak's construction for approximating a $d$-variate integral is given by the formula

$$
Q_{d, \kappa}=\sum_{i \in \mathbb{N}^{d},|i| \leq \kappa} \bigotimes_{j=1}^{d}\left(U_{i_{j}}-U_{i_{j}-1}\right),
$$

where $|\boldsymbol{i}|=i_{1}+i_{2}+\cdots+i_{d}, U_{0}$ is the zero algorithm, and each $U_{i}$ for $i \geq 1$ is a (composite) trapezoidal rule with $2^{i}+1$ equally spaced points $t_{i, k}=-1 / 2+k / 2^{i}, k=0, \ldots, 2^{i}$. Actually, we only need $2^{i}$ evaluations for $U_{i}$ since for every $g \in F$ the value $g(0)=0$ is for free. Note that $Q_{1, \kappa}=U_{\kappa}$. In general, if $\kappa<d$ then $Q_{d, \kappa} \equiv 0$.

It is easy to verify that for univariate integration we have

$$
\int_{-1 / 2}^{1 / 2} g(t) \mathrm{d} t-U_{i}(g)=\int_{-1 / 2}^{1 / 2} g^{\prime}(t) K_{i}(t) \mathrm{d} t \leq\|g\|_{F}\left(\int_{-1 / 2}^{1 / 2} K_{i}^{2}(t) \mathrm{d} t\right)^{1 / 2}
$$

with $K_{i}(t)=\left(t_{i, k}+t_{i, k+1}\right) / 2-t$ if $t \in\left[t_{i, k}, t_{i, k+1}\right)$. Hence the worst case error of $U_{i}$ is the $L_{2}$ norm of $K_{i}$, which is

$$
\left\|I-U_{i}\right\|=\frac{1}{\sqrt{12}} 2^{-i} \quad \text { for } i=0,1, \ldots
$$

From [46, Lemma 1] we know that $Q_{d, \kappa}$ can be written in an equivalent form as

$$
\begin{equation*}
Q_{d, \kappa}=\sum_{i \in P(d, \kappa)}(-1)^{\kappa-|i|}\binom{d-1}{\kappa-|\boldsymbol{i}|} \bigotimes_{\ell=1}^{d} U_{i_{\ell}} \tag{38}
\end{equation*}
$$

where $P(d, \kappa)=\left\{\boldsymbol{i} \in \mathbb{N}^{d}: \kappa-d+1 \leq|\boldsymbol{i}| \leq \kappa\right\}$. Note that this holds for general building blocks $U_{i}$. From [46, Lemma 6] we then have the following proposition.

Proposition 14 For $d, \kappa \in \mathbb{N}$ with $\kappa \geq d$, the error of the trapezoidal-Smolyak algorithm is

$$
\left\|I_{\{1: d\}}-Q_{d, \kappa}\right\| \leq 2^{-\kappa-1} 3^{-d / 2} \sqrt{\binom{\kappa}{d-1}} \leq 2^{-\kappa-1} 3^{-d / 2} \sqrt{\frac{\kappa^{d-1}}{(d-1)!}}
$$

The following proposition provides bounds on the number $n(d, \kappa)$ of function evaluations used by the trapezoidal-Smolyak algorithm $Q_{d, \kappa}$.

Proposition 15 For $d, \kappa \in \mathbb{N}$ with $\kappa \geq d$ we have $n(1, \kappa)=2^{\kappa}$ and

$$
2^{\kappa-d+1} \leq n(d, \kappa) \leq 2^{\kappa-d+1} \mathrm{e}^{d / 2-1} \frac{\kappa^{d-1}}{(d-1)!} \quad \text { for } \quad d \geq 2
$$

Proof. Clearly $n(1, \kappa)=2^{\kappa}$. Let $d \geq 2$. The lower bound on $n(d, \kappa)$ is trivial. To obtain the upper bound, we count only those points used by $Q_{d, \kappa}$ that correspond to $\boldsymbol{i}=\left(i_{1}, \ldots, i_{d}\right) \in P(d, \kappa)$ in (38) with $|\boldsymbol{i}|=\kappa$, but do not count those points with any component equal to 0 . The number of points corresponding to such $\boldsymbol{i}$ with $i_{d}=1$ is $2 n(d-1, \kappa-1)$. For successive $s=2,3, \ldots, \kappa-d+1$, the number of points corresponding to $\boldsymbol{i}$ with $i_{d}=s$ that have not been counted yet is $\left(2^{s}-2^{s-1}\right) n(d-1, \kappa-s)$. This yields

$$
n(d, \kappa)=2 n(d-1, \kappa-1)+\sum_{s=2}^{\kappa-d+1} 2^{s-1} n(d-1, \kappa-s), \quad d \geq 2
$$

We now define

$$
b(d, \kappa):=\frac{n(d, \kappa)}{2^{\kappa-d+1}}, \quad \kappa \geq d \geq 1
$$

Then we have $b(1, \kappa)=1$ and

$$
\begin{equation*}
b(d, \kappa)=b(d-1, \kappa-1)+\sum_{s=d-1}^{\kappa-1} b(d-1, s), \quad d \geq 2 \tag{39}
\end{equation*}
$$

It remains to show that for $d \geq 2$

$$
\begin{equation*}
b(d, \kappa) \leq \frac{\mathrm{e}^{d / 2-1} \kappa^{d-1}}{(d-1)!} \tag{40}
\end{equation*}
$$

Since $b(2, \kappa)=\kappa$ owing to (39), inequality (40) holds for $d=2$. Suppose (40) holds for some $d \geq 2$. Using $b(d, \kappa-1) \leq b(d, \kappa)$ and the induction hypothesis, we obtain from (39) that

$$
b(d+1, \kappa)=b(d, \kappa-1)+\sum_{s=d}^{\kappa-1} b(d, s) \leq \sum_{s=d}^{\kappa} b(d, s) \leq \frac{\mathrm{e}^{d / 2-1}}{(d-1)!} \sum_{s=d}^{\kappa} s^{d-1} \leq \frac{\mathrm{e}^{(d+1) / 2-1} \kappa^{d}}{d!}
$$

where we used the fact that $x \mapsto x^{d-1}$ is a convex function so that

$$
\sum_{s=d}^{\kappa} s^{d-1} \leq \int_{d-1 / 2}^{\kappa+1 / 2} x^{d-1} \mathrm{~d} x \leq \frac{(\kappa+1 / 2)^{d}}{d} \leq \frac{\mathrm{e}^{1 / 2} \kappa^{d}}{d}
$$

and in the last inequality we used $1+y \leq e^{y}$. Thus (40) follows by induction.
We now turn to the construction of the algorithm

$$
\begin{equation*}
\overline{\mathcal{A}}_{\varepsilon}(f)=\sum_{\mathfrak{u} \in \mathcal{U}(\varepsilon, \alpha)} A_{\mathfrak{u}, n_{\mathfrak{u}}}\left(f_{\mathfrak{u}}\right) . \tag{41}
\end{equation*}
$$

(The "bar" in our notation for the algorithm $\overline{\mathcal{A}}_{\varepsilon}$ indicates that its error is slightly larger than $\varepsilon$, as we show in Theorem 16 below.) Recall that the active set $\mathcal{U}(\varepsilon, \alpha)$ is given by (26). For the constant term $f_{\emptyset}=f(0,0, \ldots)$, we define the corresponding algorithm to be the one-point rule

$$
\begin{equation*}
A_{\emptyset, n_{\emptyset}}\left(f_{\emptyset}\right):=f_{\emptyset}=f(0,0, \ldots), \quad \text { with } \quad n_{\emptyset}:=1 \tag{42}
\end{equation*}
$$

For each nonempty $\mathfrak{u} \in \mathcal{U}(\varepsilon, \alpha)$, we recall that $F_{\mathfrak{u}}$ is equivalent to $H\left(K_{d}\right)$ with $d=|\mathfrak{u}|$ after an appropriate relabeling of the variables. Therefore we define

$$
\begin{equation*}
A_{\mathfrak{u}, n_{\mathfrak{u}}}:=Q_{|\mathfrak{u}|, \kappa_{\mathfrak{u}}} \tag{43}
\end{equation*}
$$

for some $\kappa_{\mathfrak{u}}$ to be specified below. If $\kappa_{\mathfrak{u}}<|\mathfrak{u}|$ then $Q_{|\mathfrak{u}|, \kappa_{\mathfrak{u}}}$ is the zero algorithm and $n_{\mathfrak{u}}=0$; otherwise $n_{\mathfrak{u}}=n\left(|\mathfrak{u}|, \kappa_{\mathfrak{u}}\right)$ is the number of function evaluations used by the trapezoidal-Smolyak algorithm $Q_{|\mathfrak{u}|, \kappa_{\mathfrak{u}}}$, see Proposition 15.

We now express the error $\left\|I_{\mathfrak{u}}-A_{\mathfrak{u}, n_{\mathfrak{u}}}\right\|$ in the form (22), with $q \leq 1$ as is appropriate for the trapezoidal-Smolyak algorithm in this setting. Clearly the worst case error for $\mathfrak{u}=\emptyset$ is zero and so $G_{\emptyset, q}=0$. For any nonempty $\mathfrak{u} \in \mathcal{U}(\varepsilon, \alpha)$ with $\kappa_{\mathfrak{u}} \geq|\mathfrak{u}|$, we can use Propositions 14 and 15 to obtain an upper bound on $\left\|I_{\mathfrak{u}}-A_{\mathfrak{u}, n_{\mathfrak{u}}}\right\|\left(n_{\mathfrak{u}}+1\right)^{q}$, namely

$$
G_{\mathfrak{u}, q}=2^{-|\mathfrak{u}|-1+\left(\kappa_{\mathfrak{u}}-|\mathfrak{u}|+1\right) q} 3^{-|\mathfrak{u}| / 2} \mathrm{e}^{(|\mathfrak{u}| / 2-1) q}\left(\frac{\kappa_{\mathfrak{u}}^{|\mathfrak{u}|-1}}{(|\mathfrak{u}|-1)!}\right)^{1 / 2+q} .
$$

When $\kappa_{\mathfrak{u}}<|\mathfrak{u}|$ and so $n_{\mathfrak{u}}=0$, the above error bound holds with $G_{\mathfrak{u}, q}=12^{-|\mathfrak{u}| / 2}$.
For each nonempty $\mathfrak{u} \in \mathcal{U}(\varepsilon, \alpha)$, let $h_{\mathfrak{u}}$ be given by (28) with $q \leq 1$ and $G_{\mathfrak{u}, q}=1$, and define

$$
\begin{equation*}
\kappa_{\mathfrak{u}}:=|\mathfrak{u}|+\left\lfloor\log _{2} h_{\mathfrak{u}}\right\rfloor, \tag{44}
\end{equation*}
$$

so that

$$
\begin{equation*}
2^{\kappa_{\mathbf{u}}-|\mathfrak{u}|} \leq h_{\mathfrak{u}}<2^{\kappa_{\mathbf{u}}-|\mathfrak{u}|+1} . \tag{45}
\end{equation*}
$$

Then for $\kappa_{\mathfrak{u}} \geq|\mathfrak{u}|$ we have from Proposition 15 together with (45) that

$$
\begin{equation*}
h_{\mathfrak{u}}<n_{\mathfrak{u}} \leq 2 h_{\mathfrak{u}} \mathrm{e}^{|\mathfrak{u}| / 2-1} \frac{\kappa_{\mathfrak{u}}^{|\mathfrak{u}|-1}}{(|\mathfrak{u}|-1)!} . \tag{46}
\end{equation*}
$$

(Note that $n_{\mathfrak{u}}$, the number of function evaluations used by $A_{\mathfrak{u}, n_{\mathfrak{u}}}$, has the same meaning here as in Subsection 4.3, but its connection with $h_{\mathfrak{u}}$ here is different from that in Subsection 4.3.) Following (27) with $G_{\mathfrak{u}, q}=1$ and using the lower bound from (46), we obtain

$$
\begin{equation*}
\sum_{\mathfrak{u} \in \mathcal{U}(\varepsilon, \alpha)}\left|I_{\mathfrak{u}}(f)-A_{\mathfrak{u}, n_{\mathfrak{u}}}(f)\right| \leq\left(\max _{\mathfrak{u} \in \mathcal{U}(\varepsilon, \alpha)} G_{\mathfrak{u}, q}\right)\left(\sum_{\mathfrak{u} \in \mathcal{U}(\varepsilon, \alpha)} \frac{B_{\mathfrak{u}}}{h_{\mathfrak{u}}^{q}}\right) \tag{47}
\end{equation*}
$$

The upper bound from (46) yields

$$
\begin{equation*}
\sum_{\mathfrak{u} \in \mathcal{U}(\varepsilon, \alpha)} n_{\mathfrak{u}} £(|\mathfrak{u}|) \leq\left(\max _{\mathfrak{u} \in \mathcal{U}(\varepsilon, \alpha)} 2 \mathrm{e}^{|\mathfrak{u}| / 2-1} \frac{\kappa_{\mathfrak{u}}^{|\mathfrak{u}|-1}}{(|\mathfrak{u}|-1)!}\right)\left(\sum_{\mathfrak{u} \in \mathcal{U}(\varepsilon, \alpha)} h_{\mathfrak{u}} £(|\mathfrak{u}|)\right) \tag{48}
\end{equation*}
$$

From the derivation which leads to the definition of $h_{\mathfrak{u}}$ in (28), we conclude that the second factor on the right-hand side of (47) is $\varepsilon / 2$, while the second factor on the right-hand side of (48) can be bounded as in (29). This leads to the following theorem.

Theorem 16 For the reproducing kernel Hilbert space setting specified by (33), for any $\varepsilon>0, \alpha \in$ $\left(1, \alpha_{0}\right)$ and $q \leq 1$, the algorithm $\overline{\mathcal{A}}_{\varepsilon}$ with $\mathcal{U}(\varepsilon)=\mathcal{U}(\varepsilon, \alpha)$ defined by (26), $A_{\mathfrak{u}, n_{\mathfrak{u}}}$ defined by (42) and (43), and $\kappa_{\mathfrak{u}}$ defined by (44), produces an approximation to the integral $\mathcal{I}$ with error

$$
e\left(\overline{\mathcal{A}}_{\varepsilon} ; \mathcal{F}\right) \leq \varepsilon X(\varepsilon, \alpha, q)
$$

and cost

$$
\operatorname{cost}\left(\overline{\mathcal{A}}_{\varepsilon}\right) \leq\left(\frac{2}{\varepsilon}\right)^{1 / q}\left(\sum_{\mathfrak{u} \in \mathcal{U}(\varepsilon, \alpha)} B_{\mathfrak{u}}^{1 /(q+1)}\right)^{1+1 / q} \max _{\mathfrak{u} \in \mathcal{U}(\varepsilon, \alpha)} £(|\mathfrak{u}|) Y(\varepsilon, \alpha)
$$

where

$$
X(\varepsilon, \alpha, q)=\max _{\mathfrak{u} \in \mathcal{U}(\varepsilon, \alpha)} 2^{-|\mathfrak{u}|-1+\left(\kappa_{\mathfrak{u}}-|\mathfrak{u}|+1\right) q} 3^{-|\mathfrak{u}| / 2} \mathrm{e}^{(|\mathfrak{u}| / 2-1) q}\left(\frac{\kappa_{\mathfrak{u}}^{|\mathfrak{u}|-1}}{(|\mathfrak{u}|-1)!}\right)^{1 / 2+q}
$$

and

$$
Y(\varepsilon, \alpha)=\max _{\mathfrak{u} \in \mathcal{U}(\varepsilon, \alpha)} 2 \mathrm{e}^{|\mathfrak{u}| / 2-1} \frac{\kappa_{\mathfrak{u}}^{|\mathfrak{u}|-1}}{(|\mathfrak{u}|-1)!}
$$

Since $B_{\mathfrak{u}}$ of the form (37) implies $|\mathfrak{u}| \leq d(\varepsilon)=O(\ln (1 / \varepsilon) / \ln (\ln (1 / \varepsilon)))$ for $\mathfrak{u} \in \mathcal{U}(\varepsilon, \alpha)$, and since $k_{\mathfrak{u}}$ given by (44) can be shown to be of order $|\mathfrak{u}|$, we can use Stirling's formula to conclude that both $X(\varepsilon, \alpha, q)$ and $Y(\varepsilon, \alpha)$ equal

$$
(1 / \varepsilon)^{O(1 / \ln (\ln (1 / \varepsilon)))}
$$

Corollary 17 Under the conditions of Theorem 16, for $B_{\mathfrak{u}}$ of the form (37) we have

$$
e\left(\overline{\mathcal{A}}_{\varepsilon} ; \mathcal{F}\right) \leq \varepsilon^{1-\delta(\varepsilon)}
$$

where $\delta(\varepsilon)=O(1 / \ln (\ln (1 / \varepsilon)))$. Moreover, if $£(d)=\mathrm{e}^{O(d)}$ then

$$
\operatorname{cost}\left(\overline{\mathcal{A}}_{\varepsilon}\right) \leq 2^{1+1 / q}\left(\frac{1}{\varepsilon}\right)^{1 / q+\delta(\varepsilon)}\left(\sum_{\mathfrak{u} \in \mathcal{U}(\varepsilon, \alpha)} B_{\mathfrak{u}}^{1 /(q+1)}\right)^{1+1 / q}
$$

## 6 Second application: a non-Hilbert setting

Next we consider an example which is in an anchored space setting, but not in a Hilbert space setting.

### 6.1 Problem formulation

Let $D=\mathbb{R}_{+}=[0, \infty)$ and let $F$ be the space of (locally) absolutely continuous functions $g: D \rightarrow \mathbb{R}$ such that

$$
g(0)=0 \quad \text { and } \quad\|g\|_{F}:=\left\|g^{\prime}\right\|_{\infty}<\infty .
$$

The space $F_{\mathfrak{u}}$ is the completion of the $|\mathfrak{u}|$-fold algebraic tensor product of $F$ whose functions depend only on variables listed in $\mathfrak{u}$. The completion is with respect to

$$
\left\|f_{\mathfrak{u}}\right\|_{F_{\mathfrak{u}}}:=\left\|\frac{\partial^{|\mathfrak{u}|}}{\partial \boldsymbol{x}_{\mathfrak{u}}} f_{\mathfrak{u}}\right\|_{\infty} .
$$

Note that $F_{\mathfrak{u}}$ is not a Hilbert space; however it is anchored at 0 .
In the univariate case, for $g \in F$ and $x \in \mathbb{R}^{+}$we can write $g(x)=\int_{0}^{x} g^{\prime}(t) \mathrm{d} t$ and therefore $|g(x)| \leq x\left\|g^{\prime}\right\|_{\infty}$, from which it follows easily that the functional for evaluation at the point $x$ has the norm $x$. In a similar way it follows that the point evaluation functional for the finite subset $\mathfrak{u}$ has the norm $\sup _{\left\|g_{u}\right\|_{F_{u}} \leq 1}\left|g_{\mathfrak{u}}\left(\boldsymbol{x}_{\mathfrak{u}}\right)\right|=\prod_{j \in \mathfrak{u}} x_{j}$.

We are interested in approximating the weighted integral of $f \in \mathcal{F}$, where the weights are $\rho(x)=$ $\exp (-x)$ for the univariate case, and

$$
\rho_{\mathfrak{u}}\left(\boldsymbol{x}_{\mathfrak{u}}\right):=\prod_{j \in \mathfrak{u}} \exp \left(-x_{j}\right)=\exp \left(-\sum_{j \in \mathfrak{u}} x_{j}\right)
$$

for the multivariate case. The class $\mathcal{F}$ can then be defined as the set of all uniformly convergent sums of functions $f_{\mathfrak{u}} \in F_{\mathfrak{u}}$. To obtain the functional for integration, note first that for the univariate case, by integration by parts,

$$
\begin{equation*}
I(g):=\int_{0}^{\infty} f(x) \exp (-x) \mathrm{d} x=\int_{0}^{\infty} f^{\prime}(t) \exp (-t) \mathrm{d} t, \tag{49}
\end{equation*}
$$

hence the integration functional has the norm 1 , leading to $C_{\mathfrak{u}}=\left\|I_{\mathfrak{u}}\right\|=1$.

### 6.2 Smolyak's construction

We approximate the univariate integral (49) by algorithms $U_{i}$ that are weighted versions of the (composite) trapezoidal rules using the points

$$
x_{i, k}:=-2 \ln \left(1-\frac{k}{2^{i}+1}\right), \quad 0 \leq k \leq 2^{i} .
$$

Specifically, $U_{0}=0$, and for $i \geq 1$ we have $U_{i}(f)=\sum_{k=1}^{2^{i}} a_{i, k} g\left(x_{i, k}\right)$ with

$$
a_{i, k}=\frac{\mathrm{e}^{-x_{i, k+1}}-\mathrm{e}^{-x_{i, k}}}{x_{i, k+1}-x_{i, k}}-\frac{\mathrm{e}^{-x_{i, k}}-\mathrm{e}^{-x_{i, k-1}}}{x_{i, k}-x_{i, k-1}}, \quad 1 \leq k \leq 2^{i}-1, \quad \text { and } \quad a_{i, 2^{i}}=-\frac{\mathrm{e}^{-x_{i, 2^{i}}}-\mathrm{e}^{-x_{i, 2^{i}-1}}}{x_{i, 2^{i}}-x_{i, 2^{i}-1}} .
$$

It was shown in [35] that

$$
\left\|I-U_{i}\right\|<C_{1} 2^{-i} \quad \text { with } \quad C_{1}=1.00656, \quad \text { and } \quad\left\|U_{i}-U_{i-1}\right\|<2^{1-i}
$$

This perfectly fits the setting of [46, Lemmas 2 and 7]. It follows that for the corresponding Smolyak's algorithm $A_{\mathfrak{u}, n_{\mathfrak{u}}}=Q_{|\mathfrak{u}|, \kappa_{\mathfrak{u}}}$ for $|\mathfrak{u}|$-variate integrals as in (43), $\kappa_{\mathfrak{u}} \geq|\mathfrak{u}|$, we have

$$
\left\|I_{\mathfrak{u}}-A_{\mathfrak{u}, n_{\mathfrak{u}}}\right\| \leq C_{1} 2^{-\left(\kappa_{u}-|\mathfrak{u}|+1\right)}\binom{\kappa_{\mathfrak{u}}}{|\mathfrak{u}|-1}
$$

and

$$
n_{\mathfrak{u}}=n\left(|\mathfrak{u}|, \kappa_{\mathfrak{u}}\right)=2^{\kappa_{u}-|\mathfrak{u}|+1}\binom{\kappa_{\mathfrak{u}}-1}{|\mathfrak{u}|-1} \leq 2^{\kappa_{u}-|\mathfrak{u}|+1}\binom{\kappa_{\mathfrak{u}}}{|\mathfrak{u}|-1}-1 .
$$

Hence (22) holds for $q \leq 1$ with

$$
G_{\mathfrak{u}, q}=C_{1} 2^{(q-1)\left(\kappa_{\mathfrak{u}}-|\mathfrak{u}|+1\right)}\binom{\kappa_{\mathfrak{u}}}{|\mathfrak{u}|-1}^{1+q} \quad \text { if } \quad \kappa_{\mathfrak{u}} \geq|\mathfrak{u}|,
$$

and $G_{\mathfrak{u}, q}=1$ if $\kappa_{\mathfrak{u}}<|\mathfrak{u}|$ (in which case $n_{\mathfrak{u}}=0$ and $A_{\mathfrak{u}, 0}=0$ ).

### 6.3 Specializing MDM

Taking $C_{\mathfrak{u}}=1$ in (A4) and (26), and proceeding as in Subsection 5.6 we obtain a result corresponding to Corollary 17.

Corollary 18 In the setting of this section, we use the algorithm $\overline{\mathcal{A}}_{\varepsilon}$ defined by (41) with $q \leq 1$ and $h_{\mathfrak{u}}$ and $\kappa_{\mathfrak{u}}$ defined by (28) and (44). For $B_{\mathfrak{u}}$ of the form (37) with $b_{2}>\max \left(b_{1}, 1\right)$ we have

$$
e\left(\overline{\mathcal{A}}_{\varepsilon} ; \mathcal{F}\right) \leq \varepsilon^{1-\delta(\varepsilon)}
$$

where $\delta(\varepsilon)=O(1 / \ln (\ln (1 / \varepsilon)))$. Moreover, if $£(d)=\mathrm{e}^{O(d)}$ then

$$
\operatorname{cost}\left(\overline{\mathcal{A}}_{\varepsilon}\right) \leq O\left(\varepsilon^{-(1+\delta(\varepsilon))}\right) .
$$
