Abstract

A common assumption when working with randomly right censored data, is the independence between the variable of interest Y (the survival time) and the censoring variable C . This assumption, which is not testable, is however unrealistic in certain situations. Let us assume that for a given covariate X , the dependence between the variables Y and C is described via a known copula. Additionally assume that Y is the response variable of a heteroscedastic regression model $Y = m(X) + \sigma(X)\varepsilon$, where the error term ε is independent of the explanatory variable X , and the functions m and σ are ‘smooth’. An estimator of the conditional distribution of Y given X under this model is then proposed, and the asymptotic normality of this estimator is shown. The small sample performance of the estimator is also studied, and the advantages/drawbacks of this estimator with respect to competing estimators are discussed.

Keywords: Asymptotic normality, asymptotic representation, copula, dependent censoring, kernel estimator, nonparametric regression, right censoring.

1. Introduction

Consider the following nonparametric location-scale model

$$Y = m(X) + \sigma(X)\varepsilon, \quad (1)$$

where the error ε is assumed to be independent of a one dimensional covariate X . The function $m(\cdot)$ is a conditional location functional and $\sigma(\cdot)$ is a conditional scale functional representing possible heteroscedasticity. We assume that Y is a possible (given) transformation of a survival time and is subject to random right censoring, i.e. instead of observing Y we only observe (T, Δ) , where $T = \min(Y, C)$, $\Delta = I(Y \leq C)$ and C represents the censoring time. Let (T_i, X_i, Δ_i) , $i = 1, \dots, n$ be n independent vectors having the same distribution as (T, X, Δ) .

The motivation for considering model (1) comes from the fact that the model offers important advantages with respect to the completely nonparametric model when one is interested in the estimation of the conditional distribution $F(\cdot|x) = P(Y \leq \cdot | X = x)$ of Y given $X = x$. [1] showed how advantage can be taken from model (1) to estimate this conditional distribution. The advantages are especially apparent in the right tail of the distribution. In this region the completely nonparametric competitor proposed by [2] (see also [3], [4], [5], [6], [7], among others) suffers from inconsistency problems especially when censoring is heavy. This phenomenon is similar to what happens in the right tail of the Kaplan-Meier estimator in the absence of covariates. Under model (1), [1] showed that the right tail of the distribution $F(\cdot|x)$ can be well estimated for all values of X , provided there is a region of X where censoring is light. This is because under model (1) the conditional distribution $F(y|x)$ can be written as

$$F(y|x) = F_e\left(\frac{y - m(x)}{\sigma(x)}\right), \quad (2)$$

¹This research was supported by the European Research Council (2016-2021, Horizon 2020 / ERC grant agreement No. 694409), and by IAP Research Network P7/06 of the Belgian State.

where $F_e(\cdot)$ is the distribution of the error variable ε , and this error distribution is the same for all x .

Aside [1] the nonparametric estimation of the above location-scale model with censored data has also been studied in other papers. See e.g. [8], [9], [10], [11] and [12]. Instead of studying the estimation of the model, other authors have investigated testing procedures for several aspects of the model (again in the case of censored data). We refer to [13] and [14] for goodness-of-fit tests for the location respectively scale function, and to [15] for comparing regression curves under this model. Finally, semiparametric location scale models with censored data have been studied in [16, 17] among others.

Whereas all the above papers restrict attention to the case where Y and C are independent given X , we will go one step further in this paper, and consider the case where for a given value of X , the survival time and censoring time are related. The motivation for considering this situation is multifold. In many situations, the latent censoring mechanism is not of pure administrative or random nature, but is at the contrary linked (in a weak or strong way) to the survival time. This is e.g. the case when the medical condition of a patient (good or bad) makes him/her decide to leave the study or to change treatment. It is also the case in a study on the duration of unemployment, where a person might decide after long and unsuccessful attempts to find a job, to move to another region where the job market is more attractive, and hence this person will be lost to follow up. In addition, in many situations the strength of the dependence between Y and C will depend on the value of the covariate(s). Therefore, in this paper we will allow the dependence between Y and C to depend on the value of X . We will model this dependence by means of a copula function, because copulas have the attractive feature to model the dependence structure without affecting the margins (see [18]).

In the absence of covariates and leaving the marginal distributions of Y and C completely unspecified, [19] and [20] supposed that the dependence structure between Y and C is known and is described by a known copula, and they showed that the marginal distributions of Y and C are identifiable under very weak conditions. They developed an estimator of the distribution of Y , which they called the copula-graphic estimator, and which reduces to the Kaplan-Meier estimator when Y and C are independent. In the presence of covariates, [21] extended the work of [20] to the case of a fixed design regression model, and they proposed and studied an estimator of the conditional distribution $F(\cdot|x)$ for a given covariate x without assuming any model restriction on $F(\cdot|x)$. Their estimator generalizes the Beran (1981) estimator, in the sense that it reduces to Beran's estimator when the independence copula is chosen. In the case of a random design, [22] built further on the work of [21]. They proposed estimators of a location and scale function of Y given X and studied their asymptotic properties.

In this paper we will propose and study an estimator of the conditional distribution $F(\cdot|X)$ assuming that Y and C are copula dependent given X (as in [21]), and that (X, Y) satisfy the nonparametric location-scale model (1). We will do this by first estimating the marginal error distribution $F_e(\cdot)$ taking the dependence between Y and C into account. Next, the conditional distribution $F(\cdot|x)$ will be estimated via relation (2), by plugging-in the obtained estimator of F_e and the estimators of $m(\cdot)$ and $\sigma(\cdot)$ studied by [22].

Before continuing we give an overview of the paper. In the next section we introduce the precise definitions of the estimators of the error distribution and of the conditional distribution of Y given X , and we state the assumptions needed for our asymptotic results. In Section 3 we give the main results. Proofs of the main results are in Section 4. Section 5 contains results of a small sample comparison between the suggested estimator and the estimators of [1] and [21]. Additional lemmas needed for the main results are in Appendices A and B.

2. Estimation method

We start this section with a number of definitions. Let the random vector (T, X, Δ) be as defined in Section 1 and denote $F(y|x) = P(Y \leq y|X = x)$, $G(y|x) = P(C \leq y|X = x)$, $H(y|x) = P(T \leq y|X = x)$, $H^u(y|x) = P(T \leq y, \Delta = 1|X = x)$ and $F_X(x) = P(X \leq x)$. Further, denote $F_e(y) = P(\varepsilon \leq y) = P(\frac{Y-m(X)}{\sigma(X)} \leq y)$, $G_e(y|x) = P(\frac{C-m(X)}{\sigma(X)} \leq y|X = x)$, and for $E = (T - m(X))/\sigma(X)$ denote $H_e(y) = P(E \leq y)$, $H_e^u(y) = P(E \leq y, \Delta = 1)$, $H_e(y|x) = P(E \leq y|X = x)$ and $H_e^u(y|x) = P(E \leq y, \Delta = 1|X = x)$. The probability density functions of the distribution functions defined above will be denoted by the corresponding lower case letters, and for any distribution function $F(\cdot)$, we denote the corresponding survival function by $\bar{F}(\cdot) = 1 - F(\cdot)$.

As explained in Section 1, we build further on the work of [19], [20], and [21], and model the conditional depen-

dence between Y and C via a known copula C_x that is allowed to depend on the value of X :

$$P(Y > y, C > c | X = x) = C_x(1 - F(y|x), 1 - G(c|x)).$$

Moreover, we will assume that the copula belongs to the family of Archimedean copulas, which have attractive properties and which cover a broad range of different copula structures. This means that we suppose that

$$P(Y > y, C > c | X = x) = \phi_x^{-1}[\phi_x\{1 - F(y|x)\} + \phi_x\{1 - G(c|x)\}], \quad (3)$$

for an Archimedean copula generator ϕ_x , i.e. a function from $(0, 1]$ to $\mathbf{R}^+$ that is decreasing, convex and that satisfies $\phi_x(1) = 0$.

In order to construct an estimator of the conditional distribution $F(y|x)$ given in (2), we start with focusing on the error distribution $F_e(y)$. The assumption of an Archimedean copula allows to write $F_e(y)$ in the following way:

$$\bar{F}_e(y) = \phi_{(y)}^{-1} \left\{ - \int_{B_y} \int_{-\infty}^y \phi'_x(\bar{H}_e(s|x)) dH_e^u(s|x) dF_X(x) \right\} \quad (4)$$

(see Lemma 1 in Appendix A), where $\phi_{(y)}(u) = \int_{B_y} \phi_x(u) dF_X(x)$. Statement (4) holds for every nonempty set $B_y \subset A_y := \{x : \bar{H}_e(y|x) > \eta\}$ ($\eta > 0$), which will be defined later. In order to derive an estimator of $F_e(\cdot)$, we will replace the distribution functions H_e , H_e^u and F_X in (4) by corresponding estimators $\widehat{H}_e$, $\widehat{H}_e^u$ and $\widehat{F}_X$.

We start with F_X , which we estimate by the empirical distribution function $\widehat{F}_X(\cdot) = n^{-1} \sum_{i=1}^n I(X_i \leq \cdot)$. Next, to estimate H_e and H_e^u , we first need to find appropriate estimators of the functions m and σ , for which we use the following definitions:

$$m(x) = \int_0^1 F^{-1}(s|x) J(s) ds \quad \text{and} \quad \sigma^2(x) = \int_0^1 F^{-1}(s|x)^2 J(s) ds - m(x)^2, \quad (5)$$

where $F^{-1}(s|x) = \inf\{y : F(y|x) \geq s\}$ and $J(s)$ is a given score function satisfying $\int_0^1 J(s) ds = 1$.

To estimate the functions $m(x)$ and $\sigma(x)$, we replace the conditional distribution $F(y|x)$ in (5) by the conditional copula-graphic estimator, introduced by [21] and adopted to random design by [22]:

$$\widetilde{F}(y|x) = \phi_x^{-1} \left\{ - \sum_{T_i \leq y, \Delta_i=1} \left[\phi_x(\widehat{H}(T_i^-|x)) - \phi_x(\widehat{H}(T_i|x)) \right] \right\}. \quad (6)$$

Here, $\widehat{H}(y|x) = \sum_{i=1}^n W_{ni}(x, h_n) I(T_i \leq y)$ is the [23] estimator of the distribution of T given $X = x$, where

$$W_{ni}(x, h_n) = \frac{K((x - X_i)/h_n)}{\sum_{j=1}^n K((x - X_j)/h_n)}$$

are Nadaraya-Watson weights, K is a kernel function, h_n is a bandwidth sequence, and $\widehat{H}(y^-|x) = \lim_{t \uparrow y} \widehat{H}(t|x)$. This leads to

$$\widehat{m}(x) = \int_0^1 \widetilde{F}^{-1}(s|x) J(s) ds \quad \text{and} \quad \widehat{\sigma}^2(x) = \int_0^1 \widetilde{F}^{-1}(s|x)^2 J(s) ds - \widehat{m}(x)^2, \quad (7)$$

where the score function $J(s)$ is chosen in such a way that $\widehat{m}(x)$ and $\widehat{\sigma}(x)$ are consistent. The estimators $\widehat{m}(x)$ and $\widehat{\sigma}^2(x)$ have been the object of study in [22], and are generalizations of the estimators proposed by [1] to the case where Y and C are copula dependent given X .

Next, we estimate the (sub)distribution functions $H_e(y|x)$ and $H_e^u(y|x)$ by the following [23]-type estimators:

$$\widehat{H}_e(y|x) = \sum_{i=1}^n W_{ni}(x, h_n) I(\widehat{E}_i \leq y) \quad \text{and} \quad \widehat{H}_e^u(y|x) = \sum_{i=1}^n W_{ni}(x, h_n) I(\Delta_i = 1) I(\widehat{E}_i \leq y),$$

where $\widehat{E}_i = (T_i - \widehat{m}(X_i))/\widehat{\sigma}(X_i)$, $i = 1, \dots, n$.

Plugging-in the estimators $\widehat{F}_X$, $\widehat{H}_e$ and $\widehat{H}_e^u$ in (4), we obtain the following estimator of the error distribution:

$$\widehat{F}_e(y) = \widehat{\phi}_{(y)}^{-1} \left\{ - \int_{B_y} \int_{-\infty}^y \phi'_x(\widehat{H}_e(s|x)) d\widehat{H}_e^u(s|x) d\widehat{F}_X(x) \right\}, \quad (8)$$

where $\widehat{\phi}_{(y)}(u) = \int_{B_y} \phi_x(u) d\widehat{F}_X(x)$. We choose the set B_y in (8) as a subset of the set A_y , that excludes all small segments and all points near the boundary ∂R_X of the support R_X of X , that is $B_y = \operatorname{argmax}_{B \in \mathcal{B}, B \subset A_y} \lambda(B) \cap R_{X,n}$, where $R_{X,n} = \{x \in R_X, \|x - \partial R_X\| > 2ah_n\}$, $\mathcal{B} = \{B = \cup_i B_i : B \text{ is nonempty, } B_i \text{ is convex, } \lambda(B_i) \geq \beta\}$, λ is the Lebesgue measure, $\beta > 0$ is an arbitrary small constant, and $2a$ is the length of the support of the kernel K . It is easy to show that $\{x \mapsto I_B(x) : B \in \mathcal{B}\}$ is a Donsker class of functions (where $I_B(x) = I(x \in B)$). We stress that the set B_y could also be estimated, but proving the asymptotic results in Section 3 would fill the paper with very technical details with no significant contribution (for more details see Remarks 1 and 2).

Finally, (8) together with (7) lead to our final estimator:

$$\widehat{F}(y|x) = \widehat{F}_e \left(\frac{y - \widehat{m}(x)}{\widehat{\sigma}(x)} \right). \quad (9)$$

3. Asymptotic results

3.1. Definitions and assumptions

The primary objective of this section is to study the asymptotic distribution of the estimators $\widehat{F}_e(y)$ and $\widehat{F}(y|x)$, proposed in the previous section. For establishing the asymptotic representation of these estimators we will need the following functions:

$$\begin{aligned} \xi_e(E, \Delta, y|X) &= - \int_{E \wedge y}^y \phi''_X(\overline{H}_e(s|X)) dH_e^u(s|X) + \int_{-\infty}^y \phi''_X(\overline{H}_e(s|X)) H_e(s|X) dH_e^u(s|X) \\ &\quad + \phi'_X(\overline{H}_e(y|X)) I(E \leq y, \Delta = 1) - \int_{-\infty}^y \phi'_X(\overline{H}_e(s|X)) dH_e^u(s|X), \\ \xi(T, \Delta, y|X) &= \frac{-1}{\phi'_X(\overline{F}(y|X))} \left\{ \int_{-\infty}^y \phi''_X(\overline{H}(s|X)) [I(T \leq s) - H(s|X)] dH^u(s|X) \right. \\ &\quad - \phi'_X(\overline{H}(y|X)) [I(T \leq y, \Delta = 1) - H^u(y|X)] \\ &\quad \left. - \int_{-\infty}^y \phi''_X(\overline{H}(s|X)) [I(T \leq s, \Delta = 1) - H^u(s|X)] dH(s|X) \right\}, \\ \eta(T, \Delta|X) &= \int_{-\infty}^{+\infty} J(F(y|X)) \xi(T, \Delta, y|X) dy, \\ \zeta(T, \Delta|X) &= \int_{-\infty}^{+\infty} J(F(y|X)) \xi(T, \Delta, y|X) \frac{y - m(X)}{\sigma(X)} dy, \\ \gamma_1(y|X) &= - \int_{-\infty}^y \phi''_X(\overline{H}_e(s|X)) h_e(s|X) dH_e^u(s|X) + \int_{-\infty}^y \phi'_X(\overline{H}_e(s|X)) dh_e^u(s|X), \end{aligned}$$

and

$$\gamma_2(y|X) = - \int_{-\infty}^y \phi''_X(\overline{H}_e(s|X)) sh_e(s|X) dH_e^u(s|X) + \int_{-\infty}^y \phi'_X(\overline{H}_e(s|X)) d(sh_e^u(s|X)).$$

Finally, let $\tau_\eta = \inf\{y : \overline{H}_e(y) > \eta\}$ for some small $\eta > 0$. The following assumptions are important for proving the asymptotic results in the next section.

- (A1) (i) The sequence h_n satisfies $nh_n^4 = o(1)$ and $nh_n^{3+2\delta}(\log h_n^{-1})^{-1} \rightarrow \infty$ for some $\delta > 0$.
(ii) The support R_X of X is a bounded interval in $\mathcal{R}$.

- (iii) The probability density function K has compact support $[-a, a]$ for some $a > 0$, $\int uK(u)du = 0$ and K is twice continuously differentiable.

Let $\tilde{T}_x$ be any value less than the upper bound of the support of $H(\cdot|x)$ such that $\inf_{x \in R_X} (1 - H(\tilde{T}_x|x)) > 0$.

- (A2) (i) There exist $0 \leq s_0 \leq s_1 \leq 1$ such that $s_1 < \inf_x F(\tilde{T}_x|x)$, $s_0 < \inf\{s \in [0, 1] : J(s) \neq 0\}$, $s_1 > \sup\{s \in [0, 1] : J(s) \neq 0\}$ and $\inf_{x \in R_X} \inf_{s_0 \leq s \leq s_1} f(F^{-1}(s|x)|x) > 0$.
- (ii) The function J is bounded and twice continuously differentiable on the interval (s_0, s_1) , $\int_0^1 J(s)ds = 1$ and $J(s) \geq 0$ for all $0 \leq s \leq 1$.
- (A3) (i) The distribution F_X is three times continuously differentiable and $\inf_{x \in R_X} f_X(x) > 0$.
- (ii) The functions m and σ are twice continuously differentiable and $\inf_{x \in R_X} \sigma(x) > 0$.
- (A4) (i) The functions $\phi'_x(u) = \frac{\partial}{\partial u} \phi_x(u)$, $\phi''_x(u) = \frac{\partial^2}{\partial u^2} \phi_x(u)$ and $\phi_x^{(3)}(u) = \frac{\partial^3}{\partial u^3} \phi_x(u)$ exist and are continuous in $(x, u) \in R_X \times (0, 1]$.
- (ii) The functions $\ddot{\phi}_x''(u) = \frac{\partial^4}{\partial x^2 \partial u^2} \phi_x(u)$, $\dot{\phi}_x^{(3)}(u) = \frac{\partial^4}{\partial x \partial u^3} \phi_x(u)$ and $\phi_x^{(4)}(u) = \frac{\partial^4}{\partial u^4} \phi_x(u)$ exist and are continuous in $(x, u) \in R_X \times (0, 1]$.
- (iii) The function ϕ_x satisfies $\phi'_x(1) < 0$.

For a (sub)distribution function $L(y|x)$ we will use the notations $L'(y|x) = \frac{\partial}{\partial y} L(y|x)$, $\dot{L}(y|x) = \frac{\partial}{\partial x} L(y|x)$ and similar notations will be used for higher order derivatives. (In the proofs, the function $L(y|x)$ of assumption (A5) will be either $H(y|x)$, $H_e(y|x)$, $H^u(y|x)$ or $H_e^u(y|x)$.)

- (A5) (i) $L(y|x)$ is continuous in (x, y) .
- (ii) $L'(y|x)$ exists, is continuous in (x, y) and $\sup_{x,y} |yL'(y|x)| < \infty$.
- (iii) $L''(y|x)$ exists, is continuous in (x, y) and $\sup_{x,y} |y^2 L''(y|x)| < \infty$.
- (iv) $\dot{L}(y|x)$ exists, is continuous in (x, y) and $\sup_{x,y} |y\dot{L}(y|x)| < \infty$.
- (v) $\ddot{L}(y|x)$ exists, is continuous in (x, y) and $\sup_{x,y} |y^2 \ddot{L}(y|x)| < \infty$.
- (vi) $\dot{L}'(y|x)$ exists, is continuous in (x, y) and $\sup_{x,y} |y\dot{L}'(y|x)| < \infty$.
- (vii) $\ddot{L}'(y|x)$ exists, is continuous in (x, y) and $\sup_{x,y} |y\ddot{L}'(y|x)| < \infty$.
- (A6) There exist continuous and non-decreasing functions M_j with $M_j(-\infty) = 0$ and $M_j(+\infty) < \infty$ ($j = 1, \dots, 4$) such that

$$\begin{aligned} |L(y_2|x) - L(y_1|x)| &\leq |M_1(y_2) - M_1(y_1)|, \\ |\dot{L}(y_2|x) - \dot{L}(y_1|x)| &\leq |M_2(y_2) - M_2(y_1)|, \\ |L'(y_2|x) - L'(y_1|x)| &\leq |M_3(y_2) - M_3(y_1)|, \\ |L'(y_2|x)y_2 - L'(y_1|x)y_1| &\leq |M_4(y_2) - M_4(y_1)|, \end{aligned}$$

for all $x \in R_X$, $-\infty < y_1, y_2 < +\infty$.

Note that assumption (A6) comes from [7], and is required to prove an i.i.d. representation for our estimator $\widehat{F}(y|x)$, whose remainder term is negligible uniformly in x and y (for details see Lemma 11).

Throughout the rest of this paper, we let C denote a generic positive constant, whose value may differ from line to line.

3.2. Asymptotic properties of the estimator $\widehat{F}_e(y)$

We will extend the result in [1] concerning the weak convergence of the estimator of the residual distribution function under independent censoring to the case where the dependence between censoring and survival time is described via a known copula. The weak convergence of the estimator will follow from its asymptotic representation, which we give first.

Theorem 1. [Asymptotic representation for $\widehat{F}_e(y)$] Assume (A1)-(A4), and assume that (A5) and (A6) hold for $H(y|x)$ and $H^u(y|x)$. Let $y \leq \tau_\eta$. Then,

$$\widehat{F}_e(y) - F_e(y) = n^{-1} \sum_{i=1}^n k_y(T_i, \Delta_i, X_i) + R_n(y),$$

where $\sup\{|R_n(y)| : -\infty < y \leq \tau_\eta\} = o_P(n^{-1/2})$, and

$$\begin{aligned} k_y(T, \Delta, X) = & \frac{1}{\phi'_{(y)}(\bar{F}_e(y))} \left[I(X \in B_y) \xi_e(E, \Delta, y|X) + I(X \in B_y) \eta(T, \Delta|X) \frac{\gamma_1(y|X)}{\sigma(X)} + I(X \in B_y) \zeta(T, \Delta|X) \frac{\gamma_2(y|X)}{\sigma(X)} \right. \\ & + \left\{ I(X \in B_y) \int_{-\infty}^y \phi'_X(\bar{H}_e(s|X)) dH_e^u(s|X) - \int_{B_y} \int_{-\infty}^y \phi'_X(\bar{H}_e(s|X)) dH_e^u(s|X) dF_X(x) \right\} \\ & \left. + \left\{ I(X \in B_y) \phi_X(\bar{F}_e(y)) - \int_{B_y} \phi_X(\bar{F}_e(y)) dF_X(x) \right\} \right]. \end{aligned}$$

Note that if we replace B_y by R_X , $H_e(y|x)$ by $H_e(y)$, $H_e^u(y|x)$ by $H_e^u(y)$, and set $\phi_X(u) = -\log u$, the first term above corresponds to the i.i.d. representation of the usual Kaplan-Meier estimator due to [24]. Furthermore, under the same changes, the first three terms give exactly the i.i.d. representation of the estimator studied in [1] in the case of independent censoring. The second and third term come from the fact that in the estimating procedure we replaced $(T_i - m(X_i))/\sigma(X_i)$ by $(T_i - \widehat{m}(X_i))/\widehat{\sigma}(X_i)$. Finally, the fourth and fifth terms above are caused by replacing $F_X(x)$ by $\widehat{F}_X(x)$.

Corollary 1. [Weak convergence of $\widehat{F}_e(y)$] Under the assumptions of Theorem 1, the process $n^{1/2}(\widehat{F}_e(y) - F_e(y))$, $-\infty < y \leq \tau_\eta$ converges weakly to a zero-mean Gaussian process $Z(y)$ with covariance function

$$\text{Cov}(Z(y), Z(y')) = \text{Cov}(k_y(T, \Delta, X), k_{y'}(T, \Delta, X)).$$

3.3. Asymptotic properties of the estimator $\widehat{F}(y|x)$

Using the results from Theorem 1 and Corollary 1 we will show the asymptotic representation and the weak convergence of the estimator $\widehat{F}(y|x)$ of the conditional distribution under dependent censoring described via a known copula. This result will extend the results in [1] which are obtained under independent censoring, to the case of dependent censoring described by a copula model.

Theorem 2. [Asymptotic representation for $\widehat{F}(y|x)$] Assume (A1)-(A4), and assume that (A5) and (A6) hold for $H(y|x)$ and $H^u(y|x)$. Let $(y - m(x))/\sigma(x) \leq \tau_\eta$. Then,

$$\begin{aligned} \widehat{F}(y|x) - F(y|x) &= \widehat{F}_e\left(\frac{y - \widehat{m}(x)}{\widehat{\sigma}(x)}\right) - F_e\left(\frac{y - m(x)}{\sigma(x)}\right) \\ &= (nh_n)^{-1} \sum_{i=1}^n K\left(\frac{x - X_i}{h_n}\right) h_y(T_i, \Delta_i|x) + R_n(y|x), \end{aligned}$$

where $\sup\{|R_n(y|x)| : (x, y) \in \Omega\} = o_P((nh_n)^{-1/2})$, $\Omega = \{(x, y) : (y - m(x))/\sigma(x) \leq \tau_\eta, x \in \chi\}$, χ is any set in the interior of R_X , and

$$h_y(T, \Delta|x) = \left[\eta(T, \Delta|x) + \zeta(T, \Delta|x) \frac{y - m(x)}{\sigma(x)} \right] f_e\left(\frac{y - m(x)}{\sigma(x)}\right) \sigma^{-1}(x) f_X^{-1}(x).$$

Corollary 2. [Weak convergence of $\widehat{F}(y|x)$] Under the assumptions of Theorem 2, the process $(nh_n)^{1/2}(\widehat{F}(y|x) - F(y|x))$, $x \in \chi$ fixed, $(y - m(x))/\sigma(x) \leq \tau_\eta$, converges weakly to a zero-mean Gaussian process $Z(y|x)$ with covariance function

$$\text{Cov}(Z(y|x), Z(y'|x)) = f_X(x) \int K^2(u) du \text{Cov}(h_y(T, \Delta|x), h_{y'}(T, \Delta|x)|X = x).$$

Remark 1. It can be shown that all the results from this section hold (with no extra terms in the i.i.d. representations in Theorems 1 and 2), if we replace B_y by an estimator $\widehat{B}_y$ that is converging a.s. to B_y in Lebesgue measure for every fixed $-\infty < y \leq \tau_\eta$, and for which the set $\widehat{B}_y$ belongs a.s. to $\mathcal{B}$ for all $-\infty < y \leq \tau_\eta$. The required modifications of the proofs are very technical with a small contribution of novelty, and are therefore omitted.

Remark 2. Using the notation $A_y(\eta) = \{x : \overline{H}_e(y|x) > \eta\}$ and $\widehat{A}_y(\eta) = \{x : \widehat{\overline{H}}_e(y|x) > \eta\}$, one potential estimator of B_y is $\widehat{B}_y = \operatorname{argmax}_{B \in \mathcal{B}, B \subset \widehat{A}_y(\eta+a_n)} \lambda(B) \cap \{x \in R_X, \|x - \partial R_X\| > 2ah_n\}$, where $a_n = (nh_n)^{-1/2}(\log n)^{1/2+\alpha}$ and $\alpha > 0$. This estimator satisfies the conditions of Remark 1 by the following reasoning. First, because of Lemma 9, we have $P(\lim_{n \rightarrow \infty} I\{A_y(\eta + 2a_n) \subset \widehat{A}_y(\eta + a_n) \subset A_y(\eta)\} = 1) = 1$. Additionally, simple calculus shows that the function $\eta \mapsto \lambda[A_y(\eta)]$ is a right continuous function, that is $\lambda[A_y(\eta + 2a_n)] \rightarrow \lambda[A_y(\eta)]$ a.s. Hence, we have a.s. convergence in Lebesgue measure of $\lambda[\widehat{A}_y(\eta + a_n)]$ to $\lambda[A_y(\eta)]$, which implies that $\lambda[\widehat{B}_y]$ converges to $\lambda[B_y]$. On the other hand, by definition, the set $\widehat{B}_y$ belongs to $\mathcal{B}$ for all $-\infty < y \leq \tau_\eta$.

4. Proofs of main results

In this section we give the proofs of the main results from Section 3. The proofs are based on a number of technical lemmas and propositions, which can be found in [22] and Appendices A and B.

Proof of Theorem 1. [Asymptotic representation for $\widehat{F}_e(y)$] First, we will brake down $\widehat{F}_e(y) - F_e(y)$ into several terms, in such a way that each term depends on a single plug-in estimator. This decomposition will end at (15). Then, in a second step we will deal with each term in this decomposition. We start by using Lemma 1:

$$\begin{aligned} \widehat{F}_e(y) - F_e(y) &= \phi_{(y)}^{-1} \left\{ - \int_{B_y} \int_{-\infty}^y \phi'_x(\overline{H}_e(s|x)) dH_e^u(s|x) dF_X(x) \right\} - \widehat{\phi}_{(y)}^{-1} \left\{ - \int_{B_y} \int_{-\infty}^y \phi'_x(\widehat{\overline{H}}_e(s|x)) d\widehat{H}_e^u(s|x) d\widehat{F}_X(x) \right\} \\ &= \left[\phi_{(y)}^{-1}\{U(y)\} - \phi_{(y)}^{-1}\{U_n(y)\} \right] + \left[\phi_{(y)}^{-1}\{U_n(y)\} - \phi_{(y)}^{-1}\{\widetilde{U}_n(y)\} \right] + \left[\phi_{(y)}^{-1}\{\widetilde{U}_n(y)\} - \widehat{\phi}_{(y)}^{-1}\{\widetilde{U}_n(y)\} \right] \\ &:= (\text{I}) + (\text{II}) + (\text{III}), \end{aligned} \tag{10}$$

where

$$\begin{aligned} U(y) &= - \int_{B_y} \int_{-\infty}^y \phi'_x(\overline{H}_e(s|x)) dH_e^u(s|x) dF_X(x), \\ U_n(y) &= - \int_{B_y} \int_{-\infty}^y \phi'_x(\widehat{\overline{H}}_e(s|x)) d\widehat{H}_e^u(s|x) dF_X(x), \end{aligned} \tag{11}$$

and

$$\widetilde{U}_n(y) = - \int_{B_y} \int_{-\infty}^y \phi'_x(\widehat{\overline{H}}_e(s|x)) d\widehat{H}_e^u(s|x) d\widehat{F}_X(x).$$

Next, we examine each of the three terms. Starting with the first one, we have by a second order Taylor expansion:

$$(\text{I}) = \frac{1}{\phi'_{(y)}(\overline{F}_e(y))} \{U(y) - U_n(y)\} + R_{n1}^{(I)}(y),$$

where

$$R_{n1}^{(I)}(y) = \frac{\phi''_{(y)}(\phi_{(y)}^{-1}(\varepsilon_1(y)))}{2\phi'_{(y)}(\phi_{(y)}^{-1}(\varepsilon_1(y)))^3} \{U(y) - U_n(y)\}^2,$$

with $\varepsilon_1(y)$ an intermediate value between $U_n(y)$ and $U(y)$. By adding and subtracting terms, we further have that

$$\begin{aligned}
(\mathbf{I}) &= \frac{1}{\phi'_{(y)}(\bar{F}_e(y))} \left\{ \int_{B_y} \int_{-\infty}^y \left[\phi'_x(\widehat{H}_e(s|x)) - \phi'_x(\bar{H}_e(s|x)) \right] dH_e^u(s|x) dF_X(x) \right. \\
&\quad \left. + \int_{B_y} \int_{-\infty}^y \phi'_x(\bar{H}_e(s|x)) d \left[\widehat{H}_e^u(s|x) - H_e^u(s|x) \right] dF_X(x) \right\} + R_{n1}^{(I)}(y) + R_{n2}^{(I)}(y) \\
&= \frac{1}{\phi'_{(y)}(\bar{F}_e(y))} \left\{ - \int_{B_y} \int_{-\infty}^y \phi''_x(\bar{H}_e(s|x)) \left[\widehat{H}_e(s|x) - H_e(s|x) \right] dH_e^u(s|x) dF_X(x) \right. \\
&\quad \left. + \int_{B_y} \int_{-\infty}^y \phi'_x(\bar{H}_e(s|x)) d \left[\widehat{H}_e^u(s|x) - H_e^u(s|x) \right] dF_X(x) \right\} \\
&\quad + R_{n1}^{(I)}(y) + R_{n2}^{(I)}(y) + R_{n3}^{(I)}(y),
\end{aligned} \tag{12}$$

where

$$R_{n2}^{(I)}(y) = \frac{1}{\phi'_{(y)}(\bar{F}_e(y))} \int_{B_y} \int_{-\infty}^y \left[\phi'_x(\widehat{H}_e(s|x)) - \phi'_x(\bar{H}_e(s|x)) \right] d \left[\widehat{H}_e^u(s|x) - H_e^u(s|x) \right] dF_X(x),$$

and

$$R_{n3}^{(I)}(y) = \frac{1}{2\phi'_{(y)}(\bar{F}_e(y))} \int_{B_y} \int_{-\infty}^y \phi'''_x(\xi_1(s, x)) \left[\widehat{H}_e(s|x) - H_e(s|x) \right]^2 dH_e^u(s|x) dF_X(x),$$

with $\xi_1(s, x)$ between $\widehat{H}_e(s|x)$ and $\bar{H}_e(s|x)$.

Next, we examine $(\mathbf{II})$.

$$(\mathbf{II}) = \frac{1}{\phi'_{(y)}(\bar{F}_e(y))} \{U_n(y) - \widetilde{U}_n(y)\} + R_{n1}^{(II)}(y) + R_{n2}^{(II)}(y),$$

where

$$R_{n1}^{(II)}(y) = \frac{\phi''_{(y)}(\phi_{(y)}^{-1}(\varepsilon_2(y)))}{2\phi'_{(y)}(\phi_{(y)}^{-1}(\varepsilon_2(y)))^3} \{U_n(y) - \widetilde{U}_n(y)\}^2,$$

and

$$R_{n2}^{(II)}(y) = \left(\frac{1}{\phi'_{(y)}(\phi_{(y)}^{-1}(U_n(y)))} - \frac{1}{\phi'_{(y)}(\bar{F}_e(y))} \right) \{U_n(y) - \widetilde{U}_n(y)\},$$

with $\varepsilon_2(y)$ between $\widetilde{U}_n(y)$ and $U_n(y)$. Let us further decompose $(\mathbf{II})$:

$$\begin{aligned}
(\mathbf{II}) &= \frac{1}{\phi'_{(y)}(\bar{F}_e(y))} \int_{B_y} \int_{-\infty}^y \phi'_x(\bar{H}_e(s|x)) dH_e^u(s|x) d \left[\widehat{F}_X(x) - F_X(x) \right] \\
&\quad + R_{n1}^{(II)}(y) + R_{n2}^{(II)}(y) + R_{n3}^{(II)}(y) + R_{n4}^{(II)}(y),
\end{aligned} \tag{13}$$

where

$$R_{n3}^{(II)}(y) = \frac{1}{\phi'_{(y)}(\bar{F}_e(y))} \int_{B_y} \int_{-\infty}^y \left[\phi'_x(\widehat{H}_e(s|x)) - \phi'_x(\bar{H}_e(s|x)) \right] d\widehat{H}_e^u(s|x) d \left[\widehat{F}_X(x) - F_X(x) \right],$$

and

$$R_{n4}^{(II)}(y) = \frac{1}{\phi'_{(y)}(\bar{F}_e(y))} \int_{B_y} \int_{-\infty}^y \phi'_x(\bar{H}_e(s|x)) d[\widehat{H}_e^u(s|x) - H_e^u(s|x)] d[\widehat{F}_X(x) - F_X(x)].$$

Next, we examine **(III)**. By applying a second order Taylor expansion on $\widehat{\phi}_{(y)}\{\phi_{(y)}^{-1}(\widetilde{U}_n(y))\} - \widehat{\phi}_{(y)}\{\widehat{\phi}_{(y)}^{-1}(\widetilde{U}_n(y))\}$, we obtain

$$\begin{aligned} \text{(III)} &= \phi_{(y)}^{-1}(\widetilde{U}_n(y)) - \widehat{\phi}_{(y)}^{-1}(\widetilde{U}_n(y)) \\ &= \frac{1}{\widehat{\phi}'_{(y)}(\phi_{(y)}^{-1}(\widetilde{U}_n(y)))} [\widehat{\phi}_{(y)}(\phi_{(y)}^{-1}(\widetilde{U}_n(y))) - \widetilde{U}_n(y)] + R_{n1}^{(III)}(y) \\ &= \frac{1}{\phi'_{(y)}(\phi_{(y)}^{-1}(\widetilde{U}_n(y)))} [\widehat{\phi}_{(y)}(\phi_{(y)}^{-1}(\widetilde{U}_n(y))) - \widetilde{U}_n(y)] + R_{n1}^{(III)}(y) + R_{n2}^{(III)}(y) \\ &= \frac{1}{\phi'_{(y)}(\phi_{(y)}^{-1}(U(y)))} [\widehat{\phi}_{(y)}(\phi_{(y)}^{-1}(\widetilde{U}_n(y))) - \widetilde{U}_n(y)] + R_{n1}^{(III)}(y) + R_{n2}^{(III)}(y) + R_{n3}^{(III)}(y), \end{aligned}$$

where

$$\begin{aligned} R_{n1}^{(III)}(y) &= \frac{-\widehat{\phi}_{(y)}''(\xi_2(y))}{2\widehat{\phi}'_{(y)}(\phi_{(y)}^{-1}(\widetilde{U}_n(y)))} [\phi_{(y)}^{-1}(\widetilde{U}_n(y)) - \widehat{\phi}_{(y)}^{-1}(\widetilde{U}_n(y))]^2, \\ R_{n2}^{(III)}(y) &= \left[\frac{1}{\widehat{\phi}'_{(y)}(\phi_{(y)}^{-1}(\widetilde{U}_n(y)))} - \frac{1}{\phi'_{(y)}(\phi_{(y)}^{-1}(\widetilde{U}_n(y)))} \right] [\widehat{\phi}_{(y)}(\phi_{(y)}^{-1}(\widetilde{U}_n(y))) - \widetilde{U}_n(y)], \end{aligned}$$

and

$$R_{n3}^{(III)}(y) = \left(\frac{1}{\phi'_{(y)}(\phi_{(y)}^{-1}(\widetilde{U}_n(y)))} - \frac{1}{\phi'_{(y)}(\phi_{(y)}^{-1}(U(y)))} \right) [\widehat{\phi}_{(y)}(\phi_{(y)}^{-1}(\widetilde{U}_n(y))) - \widetilde{U}_n(y)],$$

with $\xi_2(y)$ between $\widehat{\phi}_{(y)}^{-1}(\widetilde{U}_n(y))$ and $\phi_{(y)}^{-1}(\widetilde{U}_n(y))$. Further, we continue with **(III)** by calculating

$$\begin{aligned} \text{(III)} &- R_{n1}^{(III)}(y) - R_{n2}^{(III)}(y) - R_{n3}^{(III)}(y) \\ &= \frac{1}{\phi'_{(y)}(\bar{F}_e(y))} \int_{B_y} \phi_x(\phi_{(y)}^{-1}(\widetilde{U}_n(y))) d[\widehat{F}_X(x) - F_X(x)] \\ &= \frac{1}{\phi'_{(y)}(\bar{F}_e(y))} \int_{B_y} \phi_x(\phi_{(y)}^{-1}(U(y))) d[\widehat{F}_X(x) - F_X(x)] + R_{n4}^{(III)}(y) \\ &= \frac{1}{\phi'_{(y)}(\bar{F}_e(y))} \int_{B_y} \phi_x(\bar{F}_e(y)) d[\widehat{F}_X(x) - F_X(x)] + R_{n4}^{(III)}(y), \end{aligned} \tag{14}$$

where

$$R_{n4}^{(III)}(y) = \frac{1}{\phi'_{(y)}(\bar{F}_e(y))} \int_{B_y} [\phi_x(\phi_{(y)}^{-1}(\widetilde{U}_n(y))) - \phi_x(\phi_{(y)}^{-1}(U(y)))] d[\widehat{F}_X(x) - F_X(x)].$$

Combining (10), (12), (13) and (14), we subsequently obtain

$$\begin{aligned}
\widehat{F}_e(y) - F_e(y) &= \frac{1}{\phi'_{(y)}(\bar{F}_e(y))} \left\{ - \int_{B_y} \int_{-\infty}^y \phi''_x(\bar{H}_e(s|x)) [\widehat{H}_e(s|x) - H_e(s|x)] dH_e^u(s|x) dF_X(x) \right. \\
&\quad + \int_{B_y} \int_{-\infty}^y \phi'_x(\bar{H}_e(s|x)) d[\widehat{H}_e^u(s|x) - H_e^u(s|x)] dF_X(x) \\
&\quad + \int_{B_y} \int_{-\infty}^y \phi'_x(\bar{H}_e(s|x)) dH_e^u(s|x) d[\widehat{F}_X(x) - F_X(x)] \\
&\quad \left. + \int_{B_y} \phi_x(\bar{F}_e(y)) d[\widehat{F}_X(x) - F_X(x)] \right\} + R_n(y) \\
&:= \frac{1}{\phi'_{(y)}(\bar{F}_e(y))} \left\{ \widehat{\Lambda}_1(y) + \widehat{\Lambda}_2(y) + \widehat{\Lambda}_3(y) + \widehat{\Lambda}_4(y) \right\} + R_n(y). \tag{15}
\end{aligned}$$

where $R_n(y) = R_{n1}^{(I)} + R_{n2}^{(I)}(y) + R_{n3}^{(I)}(y) + R_{n1}^{(II)}(y) + R_{n2}^{(II)}(y) + R_{n3}^{(II)}(y) + R_{n4}^{(II)}(y) + R_{n1}^{(III)}(y) + R_{n2}^{(III)}(y) + R_{n3}^{(III)}(y) + R_{n4}^{(III)}(y)$. Now, by applying Lemmas 2 and 3 for the main terms we get after some simple algebra that

$$\widehat{F}_e(y) - F_e(y) = \frac{1}{n} \sum_{i=1}^n k_y(T_i, \Delta_i, X_i) + R_n(y) + o_P(n^{-1/2}),$$

uniformly in $-\infty < y \leq \tau_\eta$.

Remainder terms $R_{n2}^{(I)}(y)$ and $R_{n3}^{(I)}(y)$ are $o(n^{-1/2})$ a.s. by Lemma 10 and Lemma 9, respectively. Now, by using a Taylor expansion, we can easily show that each of the other remainder terms in $R_n(y)$ can be a.s. bounded by an expression depending on the product of two of the following terms: $U_n - U$, $\widetilde{U}_n - U$, $\widehat{\phi}_{(y)} - \phi_{(y)}$, $\int_{B_y} G_n(y, x) d[\widehat{F}_X(x) - F_X(x)]$ (where G_n is a function satisfying the assumptions of Lemma 7). Since all these terms are at most $O(\max\{n^{-1/3}, (nh_n)^{-1/2}\}(\log n)^{1/2})$ a.s. by Lemmas 6 to 8, the product of two such terms leads to the required $o(n^{-1/2})$ a.s. order. $\square$

Proof of Corollary 1. We will prove the weak convergence by showing that the class of functions $\mathcal{K} = \{k_y : -\infty < y \leq \tau_\eta\}$ from Theorem 1 is a Donsker class. The function $x \mapsto [\phi'_{(y)}(\bar{F}_e(y))]^{-1}$ is a uniformly bounded, deterministic function because of assumptions (A3)(i), (A4)(iii) and because B_y is nonempty for all $-\infty < y \leq \tau_\eta$. The term inside the square brackets in the definition of k_y belongs to a sum of Donsker classes (see (15) and Lemmas 2 and 3), which is also a Donsker class by Example 2.10.7 in [25]. Furthermore, it is easy to show that k_y is uniformly bounded. Hence, since multiplying uniformly bounded functions preserves the Donsker property (by Example 2.10.8 in [25]), the class of functions $\mathcal{K}$ is Donsker. $\square$

Proof of Theorem 2. [Asymptotic representation for $\widehat{F}(y|x)$] Write

$$\begin{aligned}
\widehat{F}(y|x) - F(y|x) &= \left[\widehat{F}_e\left(\frac{y - \widehat{m}(x)}{\widehat{\sigma}(x)}\right) - F_e\left(\frac{y - \widehat{m}(x)}{\widehat{\sigma}(x)}\right) \right] + \left[F_e\left(\frac{y - \widehat{m}(x)}{\widehat{\sigma}(x)}\right) - F_e\left(\frac{y - m(x)}{\widehat{\sigma}(x)}\right) \right] \\
&\quad + \left[F_e\left(\frac{y - m(x)}{\widehat{\sigma}(x)}\right) - F_e\left(\frac{y - m(x)}{\sigma(x)}\right) \right] \\
&= \alpha_n^1(x, y) + \alpha_n^2(x, y) + \alpha_n^3(x, y).
\end{aligned}$$

Note that $(nh_n)^{1/2} \alpha_n^1(x, y) = o_P(1)$ uniformly in $(x, y) \in \Omega$, because of the weak convergence result established in Corollary 1. For $\alpha_n^2(x, y)$ we have

$$\alpha_n^2(x, y) = -\frac{\widehat{m}(x) - m(x)}{\widehat{\sigma}(x)} f_e\left(\frac{y - m(x)}{\widehat{\sigma}(x)}\right) + \frac{1}{2} \left(\frac{\widehat{m}(x) - m(x)}{\widehat{\sigma}(x)}\right)^2 f'_e(\xi_x),$$

for some ξ_x between $(y - m(x))/\widehat{\sigma}(x)$ and $(y - \widehat{m}(x))/\widehat{\sigma}(x)$. The second term above is of order $O((nh_n)^{-1} \log n)$ a.s. by Proposition 3.5 in [22], together with the boundedness of f'_e (which follows from assumption (A5)(ii)). For the

first term, we first replace $\widehat{\sigma}(x)$ by $\sigma(x)$ by using Proposition 3.5 and then apply Proposition 3.8 in [22] to obtain an asymptotic representation. For $\alpha_n^3(x, y)$ we have

$$\alpha_n^3(x, y) = \frac{\sigma(x) - \widehat{\sigma}(x)}{\widehat{\sigma}(x)} \frac{y - m(x)}{\sigma(x)} f_e \left(\frac{y - m(x)}{\sigma(x)} \right) + \frac{1}{2} \left(\frac{\widehat{\sigma}(x) - \sigma(x)}{\widehat{\sigma}(x)} \right)^2 \left(\frac{y - m(x)}{\sigma(x)} \right)^2 f_e'(\xi_{2x}),$$

where ξ_{2x} is between $(y - m(x))/\sigma(x)$ and $(y - m(x))/\widehat{\sigma}(x)$. The second term above is $O((nh_n)^{-1} \log n)$ a.s. by Proposition 3.5 in [22], the fact that $\sup_y |y^2 f_e'(y)| < \infty$ and assumption (A3)(ii). After replacing $\widehat{\sigma}$ with σ by using again Proposition 3.5 in [22], the first term above has an asymptotic representation given by Proposition 3.8 in [22]. This combined with the asymptotic representation for $\alpha_n^2(x, y)$ completes the proof. $\square$

Proof of Corollary 2. The proof is similar to the proof of Corollary 3.4. in [1]. It suffices in fact to replace the function ξ defined in [1] by the function ξ defined in Section 3.1. Apart from this, the proof is identical. $\square$

5. Simulations

In this section we illustrate the finite sample behavior of our estimator $\widehat{F}(y|x)$ by means of Monte Carlo simulations. We compare the estimator $\widehat{F}(y|x)$ proposed in this paper with the estimator $\widetilde{F}(y|x)$ proposed by [21] and defined in (6). We expect that under the assumption of the location-scale model (1), the estimator $\widehat{F}(y|x)$ outperforms $\widetilde{F}(y|x)$. Further, the estimator $\widehat{F}(y|x)$ is a generalization of the estimator proposed by [1] and the two will be compared under the assumptions of the latter estimator, that is under independence between Y and C given X . We expect that they perform similarly.

To compare the performance of the estimators we use the mean squared error (MSE) and the integrated mean squared error ($IMSE$), to be defined further on. The simulations are carried out for samples of size $n = 100$, $n = 200$ and $n = 400$, and the results are obtained by using 500 Monte Carlo simulations.

In the first setting, we generate i.i.d. data from the following regression model:

$$Y = 8(X - 0.5)^2 + 0.5\varepsilon,$$

where X has a uniform distribution on $[0, 1]$ and the error ε has a standard normal distribution and is independent of X . The censoring variable C satisfies $C = \alpha_1(X - 0.5)^2 + \alpha_2 + 0.5\bar{\varepsilon}$, where $\bar{\varepsilon}$ is standard normal and independent of X , and the constants α_1 and α_2 are chosen so that the global censoring rate is 45% and the local censoring rate (for a fixed value of x) is between 42% and 48%. Finally, to model the dependence between Y and C given $X = x$ (i.e. the dependence between ε and $\bar{\varepsilon}$ given $X = x$) we use a Gumbel copula:

$$C_x(u_1, u_2) = \exp \left\{ - \left[-(\log u_1)^{\gamma(x)} - (\log u_2)^{\gamma(x)} \right]^{1/\gamma(x)} \right\}, \quad (16)$$

where $\gamma(x) = \max(5 - 5x, 1)$. This means that the corresponding Archimedean copula generator equals $\phi_x(u) = (-\log u)^{\gamma(x)}$. Under this setting the conditional dependence between Y and C given $X = x$ decreases from strong positive dependence to complete independence as x goes from 0 to 1 (Kendall's tau coefficient decreases from 0.8 to 0). We work with the set $B_y = A_y$ where $\eta = 0.01$ in the definition of A_y , and with the score function $J(s) = b^{-1}I(0 \leq s \leq b)$. In order to estimate the functionals $m(\cdot)$ and $\sigma(\cdot)$ consistently the constant b has to be smaller than or equal to $\inf_{x \in R_X} \widehat{F}(+\infty|x)$. Therefore, we choose $b = 0.8$ which is smaller than the average of 1000 simulated infima. Note that an equivalent way of writing the estimator $\widehat{\sigma}^2(x)$ is

$$\widehat{\sigma}^2(x) = \sum_{i=1}^n [Y_i - \widehat{m}(x)]^2 [\widetilde{F}_b(Y_i|x) - \widetilde{F}_b(Y_i^-|x)] J(\widetilde{F}_b(Y_i|x)),$$

where $\widetilde{F}_b(y|x) := \min\{\widetilde{F}(y|x), b\}$, and this is close to

$$\sum_{i=1}^n [Y_i - \widehat{m}(X_i)]^2 [\widetilde{F}_b(Y_i|x) - \widetilde{F}_b(Y_i^-|x)] J(\widetilde{F}_b(Y_i|x)).$$

Figure 1: MSE of $\widehat{F}(y|x)$ (solid line) and $\widetilde{F}(y|x)$ (dashed line) for samples of size $n = 100$, $n = 200$ and $n = 400$ (row 1, row 2, row 3) and for covariate $x = 0.2$, $x = 0.5$ and $x = 0.8$ (column 1, column 2, column 3). The number under the curve represents the ratio of the approximated $IMSE$ of $\widetilde{F}(\cdot|x)$ and $\widehat{F}(\cdot|x)$.

In the sequel we work with the latter estimator, since simulations showed that it outperforms the former (which is expected, since $Y_i - m(X_i)$ is a proper ‘error’, whereas $Y_i - m(x)$ is not). Also, we can easily show that both estimators are asymptotically equivalent under certain assumptions on the bandwidth.

For the weights that appear in our estimators $\widehat{F}(y|x)$ and $\widetilde{F}(y|x)$ we use the kernel function $K(u) = (15/16)(1 - u^2)^2 I(|u| \leq 1)$. For a fixed x , to select a bandwidth for $\widetilde{F}(\cdot|x)$, we minimize the integrated mean squared error $IMSE(\widetilde{F}(\cdot|x)) := E[\int \{\widetilde{F}(y|x) - F(y|x)\}^2 dF(y|x)]$ over a grid of 12 equidistant possible values of h_n between 0.075 and 0.350. The so-obtained estimator is denoted by $h_n(\widetilde{F}(\cdot|x))$. To calculate $IMSE(\widetilde{F}(\cdot|x))$, we use 500 simulated data sets. For each simulated data set, we compute the integrated squared error $\int \{\widetilde{F}(y|x) - F(y|x)\}^2 dF(y|x)$, and we approximate $IMSE(\widetilde{F}(\cdot|x))$ by taking the average over these 500 values. On the other hand, to estimate $\widehat{F}(\cdot|x)$ we need to choose 4 bandwidths corresponding to $\widehat{m}(\cdot)$, $\widehat{\sigma}(\cdot)$, $\widehat{H}_e(\cdot|x)$ and $\widehat{H}_e^u(\cdot|x)$. In the first step we choose bandwidths $h_n(\widehat{m})$ and $h_n(\widehat{\sigma})$ for $\widehat{m}(\cdot)$ and $\widehat{\sigma}(\cdot)$, so that they minimize the approximated $IMSE(\widehat{m}) := E[\int_{0.2}^{0.8} \{\widehat{m}(x) - m(x)\}^2 dF_X(x)]$ and $IMSE(\widehat{\sigma})$, respectively, where, by abuse of notation, $IMSE$ is used to denote both the integrated mean squared error of $\widehat{m}$, $\widehat{\sigma}$, $\widetilde{F}(\cdot|x)$ and $\widehat{F}(\cdot|x)$. Note that we do not take into account values of x close to the boundary of the support of X to avoid boundary effects of the Nadaraya-Watson weights. We calculate the approximated $IMSE(\widehat{m})$ and $IMSE(\widehat{\sigma})$ by using the same approach as for calculating the approximated $IMSE(\widetilde{F}(\cdot|x))$. In the next step we choose the same bandwidth for both $\widehat{H}_e(\cdot|x)$ and $\widehat{H}_e^u(\cdot|x)$ so that it minimizes the corresponding approximated $IMSE(\widehat{F}(\cdot|x))$ (where $\widehat{F}(\cdot|x)$ uses the bandwidths $h_n(\widehat{m})$ and $h_n(\widehat{\sigma})$ for $\widehat{m}$ and $\widehat{\sigma}$, obtained in the previous step). This bandwidth is denoted by $h_n(\widehat{F}(\cdot|x))$.

Figure 1 shows the MSE of $\widetilde{F}(y|x)$ and $\widehat{F}(y|x)$ for bandwidths chosen by the above procedure. Each subgraph contains the ratio of the approximated $IMSE$ of $\widetilde{F}(\cdot|x)$ and $\widehat{F}(\cdot|x)$, which shows that $\widehat{F}(\cdot|x)$ outperforms $\widetilde{F}(\cdot|x)$ for all sample sizes and all values of the covariate. We believe that this is a consequence of the fact that $\widehat{F}(y|x)$ uses the extra information given by the location-scale regression model (1). One could argue that in this comparison, having

Figure 2: MSE of $\widehat{F}(y|x)$ (solid lines) and $\widetilde{F}(y|x)$ (dashed lines) for samples of size $n = 100$, $n = 200$ and $n = 400$ (row 1, row 2, row 3) and for covariate $x = 0.2$, $x = 0.5$ and $x = 0.8$ (column 1, column 2, column 3). Every subgraph contains the curves of $\widehat{F}(\cdot|x)$ and $\widetilde{F}(\cdot|x)$ for different values of the bandwidth ranging from 0.075 to 0.350 (with increments of 0.025). The bandwidths for estimating $m(\cdot)$ and $\sigma(\cdot)$ are taken equal to $h_n(\widehat{m})$ and $h_n(\widehat{\sigma})$ respectively.

two optimization steps for choosing the bandwidths for $\widehat{F}(\cdot|x)$ gives an unfair advantage over a one step optimization for choosing the bandwidth for $\widetilde{F}(\cdot|x)$. To address this issue, in Figure 2, we plot the *MSE* of $\widetilde{F}(y|x)$ and of $\widehat{F}(y|x)$ for several bandwidths ranging from 0.075 to 0.350. To estimate m and σ we use the optimal bandwidths $h_n(\widehat{m})$ and $h_n(\widehat{\sigma})$ for all curves. Figure 2 shows that the second optimization step has little influence on the performance of the estimator $\widetilde{F}(y|x)$, which once again shows the advantage of our estimator $\widehat{F}(y|x)$ over $\widetilde{F}(y|x)$.

Figure 3 shows the *MSE* of the estimator $\check{F}(y|x)$ and the estimator $\widehat{F}(y|x)$ under the assumption that Y and C are independent given X (i.e. in (16) we use the independent copula). The estimator $\check{F}(y|x)$ is defined by relation (9), when $\phi_x(t) = -\log t$ (which is used in estimating $\widehat{m}$ and $\widehat{\sigma}$, that is in estimating $\widehat{F}$), and $\widehat{F}_e$ is replaced by

$$\check{F}_e(y) := 1 - \prod_{\widehat{E}_i \leq y, \Delta_i = 1} \left(1 - \frac{1}{n - i + 1} \right).$$

Note that we use the same $\widehat{m}$ and $\widehat{\sigma}$ as plug-in estimators for $\check{F}(\cdot|x)$ as we do for $\widehat{F}(\cdot|x)$. The only bandwidth selection for $\check{F}(\cdot|x)$ is the one used for $\widehat{m}$ and $\widehat{\sigma}$, and is obtained as above. The second-step bandwidth for $\widehat{F}(\cdot|x)$ is chosen from the grid $[0.075, 0.350]$ as before, so that it minimizes $IMSE(\widehat{F}(\cdot|x))$. As expected, we see that the *MSE* of the estimators $\widehat{F}(y|x)$ and $\check{F}(y|x)$ are virtually identical, with the ratio of the approximated *IMSE* of $\widehat{F}(\cdot|x)$ and $\check{F}(\cdot|x)$ approaching 1, as the sample size increases.

Figure 3: MSE of $\check{F}(y|x)$ (dashed line) and $\widehat{F}(y|x)$ (solid line) for samples of size $n = 100$, $n = 200$ and $n = 400$ (row 1, row 2, row 3) and for covariate $x = 0.2$, $x = 0.5$ and $x = 0.8$ (column 1, column 2, column 3). The number under the curve represents the ratio of the approximated $IMSE$ of $\check{F}(\cdot|x)$ and $\widehat{F}(\cdot|x)$.

Appendix A.

Appendices A and B contain the results needed for the proof of Theorem 1. Lemma 1 is a small technical result that helps to break down $\widehat{F}_e(y) - F_e(y)$ into a sum of terms each depending only on one plug-in estimator, and remainder terms (see (15)). The two main lemmas in this section are Lemmas 2 and 3, which derive asymptotic representations for the main terms in the representation of $\widehat{F}_e(y) - F_e(y)$, while Appendix B contains the results needed for showing the negligibility of the remainder terms.

In the proofs of Lemmas 2 and 3 we use empirical process theory. The result that we use most frequently is Lemma 5, which is an adaptation of a result in [26] to our framework. This result is allowing us to asymptotically approximate sums of the form $\sum_{i=1}^n \int \widehat{g}_y(x, V_i) W_{ni}(x, h_n) dF_X(x)$ by $\frac{1}{n} \sum_{i=1}^n \widehat{g}_y(X_i, V_i) + o_P(n^{-1/2})$, where $V_i = (X_i, T_i)$. Lemma 4 is used to show the Donsker property of classes of functions appearing in the proofs of Lemmas 2 and 3.

Before proceeding, we define a certain set of functions that will be used throughout Appendix A:

$$\begin{aligned} C_M^\alpha(R_X) &:= \{f : R_X \mapsto R : \|f\|_\alpha < M\}, \\ \widetilde{C}_M^\alpha(R_X) &:= \{f \in C_M^\alpha(R_X) : \inf_{x \in R_X} f(x) > b_{\inf}\}, \end{aligned} \tag{A.1}$$

where $0 < M < \infty$, $b_{\inf} = \inf_{x \in R_X} \sigma(x)/2$ and

$$\|f\|_\alpha := \max_{k \leq [\alpha]} \sup_{x \in R_X} |f^{(k)}(x)| + \sup_{x_1, x_2 \in R_X} |f^{[\alpha]}(x_1) - f^{[\alpha]}(x_2)| |x_1 - x_2|^{-(\alpha - [\alpha])},$$

where $[\alpha]$ is the greatest integer smaller than α .

The following lemma gives a specific form for the error distribution F_e , which we use to construct the estimator $\widehat{F}_e$.

Lemma 1. Assume that $H(y|x)$ and $H^u(y|x)$ satisfy (A5)(ii) and let $\phi'_x(u)$ exist for $(x, u) \in R_X \times (0, 1]$. Then for every $y \leq \tau_\eta$,

$$\overline{F}_e(y) = \phi_{(y)}^{-1} \left\{ - \int_{B_y} \int_{-\infty}^y \phi'_x(\overline{H}_e(s|x)) dH_e^u(s|x) dF_X(x) \right\}.$$

Proof. Define

$$\overline{H}_e(y_1, y_2|x) = P \left(\frac{Y - m(X)}{\sigma(X)} > y_1, \frac{C - m(X)}{\sigma(X)} > y_2 \middle| X = x \right).$$

Then, using relation (3), we can easily show that $\overline{H}_e(y_1, y_2|x) = \phi_x^{-1} \{ \phi_x(\overline{F}_e(y_1)) + \phi_x(\overline{G}_e(y_2|x)) \}$. Using [27], for all $y \leq \tau_\eta$ we get

$$H_e^{u'}(y|x) = - \frac{d}{dy_1} \overline{H}_e(y_1, y_2|x) \Big|_{y_1=y_2=y} = - \frac{\phi'_x(\overline{F}_e(y)) \overline{F}'_e(y)}{\phi'_x(\overline{H}_e(y|x))}.$$

For every x such that $\overline{H}_e(y|x) > \eta$ this leads to

$$- \int_{-\infty}^y \phi'_x(\overline{H}_e(s|x)) dH_e^u(s|x) = \int_{-\infty}^y \phi'_x(\overline{F}_e(s)) \overline{F}'_e(s) ds = \int_1^{\overline{F}_e(y)} \phi'_x(w) dw = \phi_x(\overline{F}_e(y)).$$

Now, by integrating over the set B_y with respect to $dF_X(x)$, and solving for $F_e(y)$ we finish the proof. $\square$

In the next two lemmas we establish i.i.d. representations for the terms $\widehat{\Lambda}_1(y)$, $\widehat{\Lambda}_2(y)$, $\widehat{\Lambda}_3(y)$ and $\widehat{\Lambda}_4(y)$ given in (15). These representations are needed for the i.i.d. representation of $\widehat{F}_e(y) - F_e(y)$ given in Theorem 1.

Lemma 2. [Asymptotic representation for $\widehat{\Lambda}_1(y)$] Assume (A1)-(A4), and assume that (A5) holds for $H(y|x)$ and $H^u(y|x)$. Then for $y \leq \tau_\eta$,

$$\widehat{\Lambda}_1(y) = \frac{1}{n} \sum_{i=1}^n g_y^{(1)}(X_i, T_i, \Delta_i) + R_n(y),$$

where $g_y^{(1)}(X, T, \Delta) = I(X \in B_y) \int_{-\infty}^y \phi''_X(\overline{H}_e(s|X)) \left[-\frac{h_e(s|X)}{\sigma(X)} \{ s\zeta(T, \Delta|X) + \eta(T, \Delta|X) \} - I(E \leq s) + H_e(s|X) \right] dH_e^u(s|X)$, $\sup_{y \leq \tau_\eta} |R_n(y)| = o_P(n^{-1/2})$ and $\widehat{\Lambda}_1(y)$ is defined in (15). Furthermore, the class of functions $\mathcal{G}^{(1)} = \{(x, t, \delta) \mapsto g_y^{(1)}(x, t, \delta) : -\infty < y \leq \tau_\eta\}$ is a Donsker class of functions.

Proof. By using the notation

$$g_{y, \widehat{m}, \widehat{\sigma}}^{[1]}(x_1, x_2, t) = I(x_1 \in B_y) \int_{-\infty}^y \phi''_{x_1}(\overline{H}_e(s|x_1)) \left[H_e(s|x_1) - I\left(\frac{t - \widehat{m}(x_2)}{\widehat{\sigma}(x_2)} \leq s\right) \right] h_e^u(s|x_1) ds,$$

we can write

$$\begin{aligned} \widehat{\Lambda}_1(y) &= \sum_{i=1}^n \int_{B_y} \int_{-\infty}^y \phi''_x(\overline{H}_e(s|x)) \left[H_e(s|x) - I(\widehat{E}_i \leq s) \right] h_e^u(s|x) ds W_{ni}(x, h_n) f_X(x) dx \\ &= \sum_{i=1}^n \int g_{y, \widehat{m}, \widehat{\sigma}}^{[1]}(x, X_i, T_i) W_{ni}(x, h_n) f_X(x) dx. \end{aligned}$$

Now, thanks to Lemma 5 we have

$$\begin{aligned} \widehat{\Lambda}_1(y) &= \frac{1}{n} \sum_{i=1}^n g_{y, \widehat{m}, \widehat{\sigma}}^{[1]}(X_i, X_i, T_i) + o_P(n^{-1/2}) \\ &= \frac{1}{n} \sum_{i=1}^n I(X_i \in B_y) \int_{-\infty}^y \phi''_{X_i}(\overline{H}_e(s|X_i)) \left[H_e(s|X_i) - I(\widehat{E}_i \leq s) \right] h_e^u(s|X_i) ds + o_P(n^{-1/2}). \end{aligned}$$

By adding and subtracting terms we get,

$$\begin{aligned}\widehat{\Lambda}_1(y) &= \frac{1}{n} \sum_{i=1}^n I(X_i \in B_y) \int_{-\infty}^y \phi''_{X_i}(\overline{H}_e(s|X_i)) [I(E_i \leq s) - I(\widehat{E}_i \leq s)] h_e^u(s|X_i) ds \\ &\quad + \frac{1}{n} \sum_{i=1}^n I(X_i \in B_y) \int_{-\infty}^y \phi''_{X_i}(\overline{H}_e(s|X_i)) [H_e(s|X_i) - I(E_i \leq s)] h_e^u(s|X_i) ds + o_P(n^{-1/2}) \\ &= \widehat{\Lambda}_{11}(y) + \widehat{\Lambda}_{12}(y) + o_P(n^{-1/2}).\end{aligned}\tag{A.2}$$

The second term on the right hand side is of the desired form, and the corresponding class of functions $\{(x, t, \delta) \mapsto I(x \in B_y) \int_{-\infty}^y \phi''_x(\overline{H}_e(s|x)) [H_e(s|x) - I(\frac{t-m(x)}{\sigma(x)} \leq s)] h_e^u(s|x) ds : -\infty < y \leq \tau_\eta\}$ is a Donsker class by Lemma 4. To deal with the term $\widehat{\Lambda}_{11}(y)$, we define the class of functions

$$\mathcal{G}^{[2]} := \left\{ (x, t) \mapsto g_{y, m_1, \sigma_1}^{[2]}(x, t) : y \leq \tau_\eta, m_1 \in C_M^{1+\delta}, \sigma_1 \in \widetilde{C}_M^{1+\delta} \right\},$$

where $g_{y, m_1, \sigma_1}^{[2]}(x, t) = I(x \in B_y) \int_{-\infty}^y \phi''_x(\overline{H}_e(s|x)) [I(\frac{t-m(x)}{\sigma(x)} \leq s) - I(\frac{t-m_1(x)}{\sigma_1(x)} \leq s)] h_e^u(s|x) ds$. The class of functions $\mathcal{G}^{[2]}$ is Donsker by Lemma 4. Therefore, by Corollary 2.3.12 in the book of [25] we have

$$\lim_{\alpha \downarrow 0} \limsup_{n \rightarrow \infty} P \left(\sup_{g^{[2]} \in \mathcal{G}^{[2]}, \text{Var}(g^{[2]}) < \alpha} n^{-1/2} \left| \sum_{i=1}^n g^{[2]}(X_i, T_i) - E[g^{[2]}(X, T)] \right| > \varepsilon \right) = 0,$$

for every $\varepsilon > 0$. Since it follows from Propositions 3.5, 3.6 and 3.7 in [22] that $\lim_{n \rightarrow \infty} P(g_{y, \widehat{m}, \widehat{\sigma}}^{[2]} \in \mathcal{G}^{[2]}) = 1$, and since it can be easily verified that $\text{Var}(g_{y, \widehat{m}, \widehat{\sigma}}^{[2]}(X, T)) = o(1)$ a.s., we can approximate $g_{y, \widehat{m}, \widehat{\sigma}}^{[2]}$ in $\widehat{\Lambda}_{11}(y)$ by its expectation:

$$\widehat{\Lambda}_{11}(y) = E \left\{ I(X \in B_y) \int_{-\infty}^y \phi''_X(\overline{H}_e(s|X)) [I(E \leq s) - I(\widehat{E} \leq s)] h_e^u(s|X) ds \right\} + o_P(n^{-1/2}).$$

Further, we calculate

$$\begin{aligned}\widehat{\Lambda}_{11}(y) - o_P(n^{-1/2}) &= \int_{-\infty}^y \int_{B_y} \phi''_x(\overline{H}_e(s|x)) h_e^u(s|x) \left[P(E \leq s|X=x) - P(\widehat{E} \leq s|\mathcal{X}_n, X=x) \right] dF_X(x) ds \\ &= \int_{-\infty}^y \int_{B_y} \phi''_x(\overline{H}_e(s|x)) h_e^u(s|x) \left[P(E \leq s|X=x) - P\left(\frac{T - \widehat{m}(x)}{\widehat{\sigma}(x)} \leq s \middle| X=x\right) \right] dF_X(x) ds \\ &= \int_{-\infty}^y \int_{B_y} \phi''_x(\overline{H}_e(s|x)) h_e^u(s|x) \left[H_e(s|x) - H_e\left(\frac{s\widehat{\sigma}(x) + \widehat{m}(x) - m(x)}{\sigma(x)} \middle| x\right) \right] dF_X(x) ds \\ &= - \int_{-\infty}^y \int_{B_y} \phi''_x(\overline{H}_e(s|x)) h_e^u(s|x) \frac{h_e(s_1|x)}{\sigma(x)} \{s[\widehat{\sigma}(x) - \sigma(x)] + \widehat{m}(x) - m(x)\} dF_X(x) ds \\ &\quad - \frac{1}{2} \int_{-\infty}^y \int_{B_y} \phi''_x(\overline{H}_e(s|x)) h_e^u(s|x) \frac{h_e'(s_1|x)}{\sigma(x)^2} \{s[\widehat{\sigma}(x) - \sigma(x)] + \widehat{m}(x) - m(x)\}^2 dF_X(x) ds,\end{aligned}$$

where s_1 is between s and $\sigma(x)^{-1}[s\widehat{\sigma}(x) + \widehat{m}(x) - m(x)]$, and $\mathcal{X}_n = \{(T_i, \Delta_i, X_i) : i = 1, \dots, n\}$. Because of assumption (A5)(iii) we have that $\sup_{y,x} |y^2 h_e'(y|x)| < \infty$, so the second term above is of order $O((nh_n)^{-1} \log n)$ a.s. by Proposition 3.5 in [22]. By using the asymptotic representation for $\widehat{m}$ and $\widehat{\sigma}$ given in Proposition 3.8 in [22], we get

$$\begin{aligned}\widehat{\Lambda}_{11}(y) - o_P(n^{-1/2}) &= -\frac{1}{n} \sum_{i=1}^n \int_{B_y} \int_{-\infty}^y \phi''_x(\overline{H}_e(s|x)) \frac{h_e(s|x)}{\sigma(x)} [s\zeta(T_i, \Delta_i|x) + \eta(T_i, \Delta_i|x)] \frac{K\left(\frac{x-X_i}{h_n}\right)}{h_n} dH_e^u(s|x) dx \\ &:= \frac{1}{n} \sum_{i=1}^n \int g_y^{[3]}(X_i + uh_n, T_i, \Delta_i) K(u) du.\end{aligned}$$

We can write

$$g_y^{[3]}(x, t, \delta) = -I(x \in B_y) \int_{-\infty}^y q_s(x, t, \delta) dH_e^u(s|x),$$

where $q_s(x, t, \delta) = \phi_x''(\bar{H}_e(s|x)) \frac{h_e(s|x)}{\sigma(x)} [s\zeta(t, \delta|x) + \eta(t, \delta|x)]$. By assumptions (A4) and (A5)(ii,iii) we have that for every $s \leq y \leq \tau_\eta$ the function $x \mapsto \phi_x''(\bar{H}_e(s|x)) \frac{h_e(s|x)}{\sigma(x)} s$ is uniformly bounded (by a constant not depending on s and y) in $x \in B_y$, as well as the corresponding first derivative. Therefore, using the notation $\mathcal{Q} = \{x \mapsto \phi_x''(\bar{H}_e(s|x)) \frac{h_e(s|x)}{\sigma(x)} s : s \leq \tau_\eta\}$, we have that the bracketing number $N_{[\cdot]}(\varepsilon, \mathcal{Q}, L_2(P))$ equals $\exp(-C\varepsilon)$, for some constant C (see Corollary 2.7.2 in [25]). By a similar reasoning we have that the bracketing number of the class $\mathcal{Q}' = \{x \mapsto \phi_x''(\bar{H}_e(s|x)) \frac{h_e(s|x)}{\sigma(x)} : s \leq \tau_\eta\}$ equals $\exp(-C\varepsilon)$. Now, $\mathcal{Q}$ and $\mathcal{Q}'$ are Donsker by Theorem 2.5.6 in [25]. Hence, Lemma 4 entails that $\mathcal{G}^{[3]} = \{(x, t, \delta) \mapsto g_y^{[3]}(x, t, \delta) : -\infty < y \leq \tau_\eta\}$ is a Donsker class of functions, while Lemma 5 entails that

$$\widehat{\Lambda}_{11}(y) = \frac{1}{n} \sum_{i=1}^n g_y^{[3]}(X_i, T_i, \Delta_i) + o_P(n^{-1/2}).$$

Now, by using (A.2) we get $\widehat{\Lambda}_1(y) = \frac{1}{n} \sum_{i=1}^n g_y^{(1)}(X_i, T_i, \Delta_i) + o_P(n^{-1/2})$. The class of functions $\mathcal{G}^{(1)}$ is a Donsker class as it is a sum of two Donsker classes (see Example 2.10.7 in [25]), which completes the proof. $\square$

Lemma 3. [Asymptotic representation for $\widehat{\Lambda}_2(y)$, $\widehat{\Lambda}_3(y)$ and $\widehat{\Lambda}_4(y)$] Assume (A1)-(A4), and assume that (A5) holds for $H(y|x)$ and $H^u(y|x)$. Then for $y \leq \tau_\eta$,

$$\begin{aligned} \widehat{\Lambda}_2(y) &= \frac{1}{n} \sum_{i=1}^n g_y^{(2)}(X_i, T_i, \Delta_i) + R_n(y), \\ \widehat{\Lambda}_3(y) &= \frac{1}{n} \sum_{i=1}^n g_y^{(3)}(X_i, T_i, \Delta_i), \end{aligned}$$

and

$$\widehat{\Lambda}_4(y) = \frac{1}{n} \sum_{i=1}^n g_y^{(4)}(X_i, T_i, \Delta_i),$$

where

$$\begin{aligned} g_y^{(2)}(X, T, \Delta) &= I(X \in B_y) \int_{-\infty}^y \phi'_X(\bar{H}_e(s|X)) d\left[\frac{h_e^u(s|X)}{\sigma(X)} [s\zeta(T, \Delta|X) + \eta(T, \Delta|X)] + I(E \leq s, \Delta = 1) - H_e^u(s|X) \right], \\ g_y^{(3)}(X, T, \Delta) &= I(X \in B_y) \int_{-\infty}^y \phi'_X(\bar{H}_e(s|X)) dH_e^u(s|X) - \int_{B_y} \int_{-\infty}^y \phi'_x(\bar{H}_e(s|x)) dH_e^u(s|x) dF_X(x), \\ g_y^{(4)}(X, T, \Delta) &= I(X \in B_y) \phi_X(\bar{F}_e(y)) - \int_{B_y} \phi_x(\bar{F}_e(y)) dF_X(x), \end{aligned}$$

$\sup_{y \leq \tau_\eta} |R_n(y)| = o_P(n^{-1/2})$, and the terms $\widehat{\Lambda}_2(y)$, $\widehat{\Lambda}_3(y)$ and $\widehat{\Lambda}_4(y)$ are defined in (15). Furthermore, the class of functions $\mathcal{G}^{(i)} = \{(x, t, \delta) \mapsto g_y^{(i)}(x, t, \delta) : -\infty < y \leq \tau_\eta\}$ is a Donsker class of functions for every $i = 2, 3, 4$.

Proof. The expressions of $\widehat{\Lambda}_3(y)$ and $\widehat{\Lambda}_4(y)$ are obtained from simple algebra. Showing the Donsker property of $\mathcal{G}^{(3)}$ and $\mathcal{G}^{(4)}$ is very similar, and therefore we will only show it for $\mathcal{G}^{(3)}$. The first factor of the first term in $g_y^{(3)}(x, t, \delta)$ belongs to a class of functions that is Donsker by construction. The second factor of the first term in $g_y^{(3)}(x, t, \delta)$ is bounded and monotone in the parameter y , uniformly in $y \leq \tau_\eta$. Therefore, its ε -bracketing number is bounded by $C\varepsilon^{-1}$, which by Theorem 2.5.6 in [25] implies the Donsker property. The second term of $g_y^{(3)}(x, t, \delta)$ is a deterministic, uniformly bounded function in $y \leq \tau_\eta$ by (A4), and therefore trivially Donsker. Since multiplying and adding uniformly bounded

functions preserves the Donsker property (by Examples 2.10.7 and 2.10.8 in [25]), the class of functions $\mathcal{G}^{(3)}$ is also Donsker. To deal with the expression of $\widehat{\Lambda}_2(y)$ we start by using integration by parts:

$$\begin{aligned}\widehat{\Lambda}_2(y) &= \int_{B_y} \phi'_x(\overline{H}_e(y|x)) [\widehat{H}_e^u(y|x) - H_e^u(y|x)] dF_X(x) \\ &\quad + \int_{B_y} \int_{-\infty}^y \phi''_x(\overline{H}_e(s|x)) h_e(s|x) [\widehat{H}_e^u(s|x) - H_e^u(s|x)] ds dF_X(x).\end{aligned}$$

From here on the proof is very similar to the proof of Lemma 2 and is therefore omitted. $\square$

The following lemma shows the Donsker property for the classes of functions that are showing up in the proofs of Lemmas 2, 3 and 5.

Lemma 4. *Assume (A1)-(A4), and assume that (A5) holds for $H(y|x)$ and $H^u(y|x)$. Then, the following classes of functions are Donsker:*

$$\begin{aligned}\mathcal{G}_1 &= \left\{ (x_1, x_2, t) \mapsto g_{y,m_1,\sigma_1,1}(x_1, x_2, t) : y \leq \tau_\eta, m_1 \in C_M^{1+\delta}(R_X), \sigma_1 \in \widetilde{C}_M^{1+\delta}(R_X) \right\}, \\ \mathcal{G}_2 &= \left\{ (x_1, x_2, t) \mapsto g_{y,m_1,\sigma_1,2}(x_1, x_2, t) : y \leq \tau_\eta, m_1 \in C_M^{1+\delta}(R_X), \sigma_1 \in \widetilde{C}_M^{1+\delta}(R_X) \right\}, \\ \mathcal{G}_3 &= \left\{ (x, t, \delta) \mapsto g_{y,\psi,3}(x, t, \delta) : y \leq \tau_\eta, \psi \in \{\zeta, \eta\} \right\},\end{aligned}$$

and

$$\mathcal{G}_4 = \left\{ (x, t, \delta) \mapsto g_{y,\psi,4}(x, t, \delta) : y \leq \tau_\eta, \psi \in \{\zeta, \eta\} \right\},$$

where

$$\begin{aligned}g_{y,m_1,\sigma_1,1}(x_1, x_2, t) &= I(x_1 \in B_y) \int_{-\infty}^y q_s(x_1) \left[I\left(\frac{t - m_1(x_2)}{\sigma_1(x_2)} \leq s\right) - H_e(s|x_1) \right] h_e^u(s|x_1) ds, \\ g_{y,m_1,\sigma_1,2}(x_1, x_2, t) &= I(x_1 \in B_y) q_y(x_1) \left[I\left(\frac{t - m_1(x_2)}{\sigma_1(x_2)} \leq y\right) - H_e(y|x_1) \right] h_e^u(y|x_1), \\ g_{y,\psi,3}(x, t, \delta) &= I(x \in B_y) \int_{-\infty}^y q_s(x) \psi(t, \delta|x) h_e^u(s|x) ds,\end{aligned}$$

and

$$g_{y,\psi,4}(x, t, \delta) = I(x \in B_y) q_y(x) \psi(t, \delta|x) h_e^u(y|x),$$

the sets $C_M^{1+\delta}(R_X)$ and $\widetilde{C}_M^{1+\delta}(R_X)$ are defined in (A.1), and the class $\{x \mapsto q_y(x) : y \leq \tau_\eta\}$ is a Donsker class of non-negative (non-positive) functions, such that $\sup_{y \leq \tau_\eta} \sup_{x \in B_y} \{|q_y(x)|, |\frac{\partial}{\partial x} q_y(x)|\} < \infty$.

Proof. First, we will prove that the class of functions $\mathcal{G}_2$ is Donsker. Note that the class of functions $\{(x_1, x_2, t) \mapsto [I(\frac{t - m_1(x_2)}{\sigma_1(x_2)} \leq y) - H_e(y|x_1)] : y \leq \tau_\eta, m_1 \in C_M^{1+\delta}(R_X), \sigma_1 \in \widetilde{C}_M^{1+\delta}(R_X)\}$ is Donsker by calculations in Lemma A.1 in [1]. The class of functions $\{x \mapsto I_B(x) : B \in \mathcal{B}\}$ is Donsker (see Section 2). Hence, the class of functions $\mathcal{G}_2$ is Donsker since it is a product of uniformly bounded, Donsker classes of functions (see Example 2.10.8 in the book of [25]). Since it is easy to see that the functions ζ and η are uniformly bounded, $\mathcal{G}_4$ is a product of uniformly bounded, Donsker classes of functions, and therefore Donsker itself (see Example 2.10.8 in [25]).

Proving that $\mathcal{G}_1$ and $\mathcal{G}_3$ are Donsker is similar, therefore we will only prove that $\mathcal{G}_1$ is Donsker, which is the hardest of the two. We will use results from the book of [25]. By Theorem 2.5.6 in their book it is sufficient to show that

$$\int_0^\infty \sqrt{\log N_{[\cdot]}(\varepsilon, \mathcal{G}_1, \|\cdot\|_\infty)} d\varepsilon < \infty. \quad (\text{A.3})$$

We will restrict ourselves to showing (A.3) for $\mathcal{G}_1^1 = \{(x_1, x_2, t) \mapsto g_{y,m_1,\sigma_1}^1(x_1, x_2, t) : y \leq \tau_\eta, m_1 \in C_M^{1+\delta}(R_X), \sigma_1 \in \widetilde{C}_M^{1+\delta}(R_X)\}$, where $g_{y,m_1,\sigma_1}^1(x_1, x_2, t) = \int_{-\infty}^y q_s(x_1) I(\frac{t - m_1(x_2)}{\sigma_1(x_2)} \leq s) h_e^u(s|x_1) ds$. By Theorem 2.7.1 in the aforementioned

book we know that $C_M^{1+\delta}(R_X)$ and $\widetilde{C}_M^{1+\delta}(R_X)$ can be covered by $M_1 = \exp(C_1 \varepsilon^{-1/(1+\delta)})$ and $M_2 = \exp(C_2 \varepsilon^{-1/(1+\delta)})$ ε -brackets with respect to the supremum norm, respectively. Let $\{[m_j^l, m_j^r] : j = 1, \dots, M_1\}$ and $\{[\sigma_k^l, \sigma_k^r] : k = 1, \dots, M_2\}$ be those ε -brackets. Let $x_1, \dots, x_{M_3}$ be a grid of R_X such that $x_{r+1} - x_r \leq \varepsilon$, $r = 1, \dots, M_3 - 1$ and let $\{y_{ri} : r = 1, \dots, M_3, i = 1, \dots, M_4\}$ be such that $H_e^u(y_{ri+1}|x_j) - H_e^u(y_{ri}|x_j) \leq \varepsilon$. Let $\{y_i : i = 1, \dots, M_5\}$ be the union of all y_{ri} in ascending order. There are $M_5 = C\varepsilon^{-2}$ of them. Now, we define brackets $\{[g_{y_i, m_j^l, \sigma_k^l}, g_{y_{i+1}, m_j^r, \sigma_k^r}]\}_{i,j,k}$. There are at most $C\varepsilon^{-2} \exp\{C\varepsilon^{-1/(1+\delta)}\}$ of them. Hence, they satisfy condition (A.3) and they cover $\mathcal{G}_1^1$, because $g_{t, m, \sigma}^1(\cdot, \cdot)$ is a monotone function of its parameters. Now, to show that $\mathcal{G}_1^1$ is Donsker, we only need to show that the defined brackets are ε -brackets:

$$\begin{aligned} & \|g_{y_i, m_j^l, \sigma_k^l} - g_{y_{i+1}, m_j^r, \sigma_k^r}\|_\infty \\ & \leq \|g_{y_i, m_j^l, \sigma_k^l} - g_{y_i, m_j^l, \sigma_k^r}\|_\infty + \|g_{y_i, m_j^l, \sigma_k^r} - g_{y_i, m_j^r, \sigma_k^r}\|_\infty + \|g_{y_i, m_j^r, \sigma_k^r} - g_{y_{i+1}, m_j^r, \sigma_k^r}\|_\infty. \end{aligned} \quad (\text{A.4})$$

We start with the second term:

$$\begin{aligned} & \|g_{y_i, m_j^l, \sigma_k^r} - g_{y_i, m_j^r, \sigma_k^r}\|_\infty \\ & \leq C \sup_{t \leq \tau_\eta, x_1, x_2 \in R_X} \int_{-\infty}^{\infty} \left| I\left(\frac{t - m_j^l(x_2)}{\sigma_k^r(x_2)} \leq s\right) - I\left(\frac{t - m_j^r(x_2)}{\sigma_k^r(x_2)} \leq s\right) \right| h_e^u(s|x_1) ds \\ & \leq C \sup_{t \leq \tau_\eta, x_1, x_2 \in R_X} \left| H_e^u\left(\frac{t - m_j^l(x_2)}{\sigma_k^r(x_2)} \middle| x_1\right) - H_e^u\left(\frac{t - m_j^r(x_2)}{\sigma_k^r(x_2)} \middle| x_1\right) \right| \\ & \leq \|h_e^u\|_\infty \sup_{x_2 \in R_X} \left| \frac{m_j^l(x_2) - m_j^r(x_2)}{\sigma_k^r(x_2)} \right| \\ & \leq C \|m_j^l - m_j^r\|_\infty \leq C\varepsilon. \end{aligned}$$

The fourth inequality follows from (A5)(ii) for H_e^u , and the fact that σ_k is bounded away from zero as a function belonging to $\widetilde{C}_M^{1+\delta}(R_X)$. Similarly, we can bound the first term:

$$\begin{aligned} & \|g_{y_i, m_j^l, \sigma_k^l} - g_{y_i, m_j^l, \sigma_k^r}\|_\infty \leq \|h_e^u\|_\infty \sup_{y \leq \tau_\eta, x_2 \in R_X} \left| \frac{(y - m_j^l(x_2))(\sigma_k^l(x_2) - \sigma_k^r(x_2))}{\sigma_k^l(x_2)\sigma_k^r(x_2)} \right| \\ & \leq C \|\sigma_k^l - \sigma_k^r\|_\infty \leq C\varepsilon. \end{aligned}$$

The second inequality follows from (A5)(ii) for H_e^u , and the fact that σ_k and σ_l are bounded away from zero as functions belonging to $\widetilde{C}_M^{1+\delta}(R_X)$. For the third term we calculate

$$\begin{aligned} & \|g_{y_i, m_j^r, \sigma_k^r} - g_{y_{i+1}, m_j^r, \sigma_k^r}\|_\infty \leq C \sup_{x \in R_X} \int_{y_i}^{y_{i+1}} h_e^u(s|x) ds \\ & \leq C \sup_{x \in R_X} |H_e^u(y_{i+1}|x) - H_e^u(y_i|x)| \\ & \leq C \max_j |H_e^u(y_{i+1}|x_j) - H_e^u(y_i|x_j)| + 2 \sup_{y, x} |h_e^u(y|x)| \varepsilon \\ & \leq C\varepsilon. \end{aligned}$$

To get the last inequality we used the uniform boundedness of h_e^u . Now, we have that expression (A.4) is bounded by $C\varepsilon$. Because C is independent of the bracket selection (i.e. of ε), we have that the brackets $\{[g_{y_i, m_j^l, \sigma_k^l}, g_{y_{i+1}, m_j^r, \sigma_k^r}]\}_{i,j,k}$ are ε -brackets, therefore by the previous reasoning $\mathcal{G}_1^1$ (and hence $\mathcal{G}_1$) is Donsker. $\square$

The next lemma is an adaptation of the result on convergence of smoothed processes in [26] to our framework. We will use this result in the proofs of Lemmas 2 and 3 to asymptotically replace expressions of the form $\sum_{i=1}^n \int \widehat{g}_y(x, V_i) W_{ni}(x, h_n) dF_X(x)$ by the simpler expressions $\frac{1}{n} \sum_{i=1}^n \widehat{g}_y(X_i, V_i)$, where $V_i = (X_i, T_i)$.

Lemma 5. Assume the conditions and notations of Lemma 4. Then, using the notation $\widehat{g}_{y,r} := g_{y,\widehat{m},\widehat{\sigma},r}$, for $r=1,2$, and $\widehat{g}_{y,r} := g_{y,\psi,r}$, for $r=3,4$, we have

$$\sup_{y \leq \tau_\eta} \left| \frac{1}{n} \sum_{i=1}^n \left\{ \int \widehat{g}_{y,r}(X_i + uh_n, V_i) K(u) du - \widehat{g}_{y,r}(X_i, V_i) \right\} \right| = o_P(n^{-1/2}), \quad (\text{A.5})$$

$$\sup_{y \leq \tau_\eta} \left| \sum_{i=1}^n \left\{ \int \widehat{g}_{y,r}(t, V_i) W_{ni}(t, h_n) f_X(t) dt - \frac{1}{n} \widehat{g}_{y,r}(X_i, V_i) \right\} \right| = o_P(n^{-1/2}). \quad (\text{A.6})$$

Proof. Before we start, we give the results that will be used throughout the proof and which will be shown at the end of this proof. For $r = 1, 2, 3, 4$ we have

$$\sup_{g \in \mathcal{G}_r} \|g\|_\infty < \infty, \quad (\text{A.7})$$

$$\lim_{n \rightarrow \infty} P(\{\widehat{g}_{y,r} : -\infty < y \leq \tau_\eta\} \subset \mathcal{G}_r) = 1, \quad (\text{A.8})$$

$$\sup_{g \in \mathcal{G}_r} E \left[\int g(X + uh_n, V) K(u) du - g(X, V) \right]^2 = o(1), \quad (\text{A.9})$$

and

$$\sup_{y \leq \tau_\eta} \left| E \left[\int \widehat{g}_{y,r}(X + uh_n, V) K(u) du - \widehat{g}_{y,r}(X, V) \middle| \mathcal{X}_n \right] \right| = o(n^{-1/2}) \text{ a.s.}, \quad (\text{A.10})$$

where $V = (X, T)$ and $\mathcal{X}_n = \{(X_i, T_i, \Delta_i) : i = 1, \dots, n\}$. The aforementioned results also hold when we replace $\widehat{g}_{y,r}$ and $\mathcal{G}_r$ by $\widehat{g}'_{y,r} = \widehat{g}_{y,r} \frac{f_X - \widehat{f}_X}{\widehat{f}_X}$ and $\mathcal{G}'_r := \mathcal{G}_r \times C_M^{1+\delta}(R_X)$, respectively, where $\widehat{f}_X(x) = \frac{1}{nh_n} \sum_{i=1}^n K\left(\frac{X_i - x}{h_n}\right)$.

In the following calculations we will use the notation $\widehat{g}_y$ to represent $\widehat{g}_{y,r}$, for all $r = 1, 2, 3, 4$, since the proof is the same in all cases. Similarly, for all $r = 1, 2, 3, 4$, we will use the notation g for $g_r \in \mathcal{G}'_r$, and $\mathcal{G}'$ for $\mathcal{G}'_r$. Conditions (A.7) to (A.10) allow us to apply Theorem 2 (a) in [26] to the term in (A.5), which gives

$$\begin{aligned} & \sup_{y \leq \tau_\eta} \left| \frac{1}{n} \sum_{i=1}^n \left\{ \int \widehat{g}_y(t, V_i) \frac{1}{h_n} K\left(\frac{X_i - t}{h_n}\right) dt - \widehat{g}_y(X_i, V_i) \right\} \right| \\ &= \sup_{y \leq \tau_\eta} \left| E \left[\int \widehat{g}_y(t, V) \frac{1}{h_n} K\left(\frac{X - t}{h_n}\right) dt - \widehat{g}_y(X, V) \middle| \mathcal{X}_n \right] \right| + o_P(n^{-1/2}). \end{aligned}$$

The first term on the right hand side is $o(n^{-1/2})$ a.s. by (A.10), which implies (A.5). Next, to prove statement (A.6), we write

$$\begin{aligned} Q(\widehat{g}_y) &:= \sum_{i=1}^n \int \widehat{g}_y(t, V_i) W_{ni}(t, h_n) f_X(t) dt \\ &= \frac{1}{n} \sum_{i=1}^n \int \widehat{g}_y(t, V_i) \frac{f_X(t)}{\widehat{f}_X(t)} \frac{1}{h_n} K\left(\frac{X_i - t}{h_n}\right) dt \\ &= \frac{1}{n} \sum_{i=1}^n \int \widehat{g}_y(t, V_i) \frac{1}{h_n} K\left(\frac{X_i - t}{h_n}\right) dt + \frac{1}{n} \sum_{i=1}^n \int \widehat{g}_y(t, V_i) \frac{f_X(t) - \widehat{f}_X(t)}{\widehat{f}_X(t)} \frac{1}{h_n} K\left(\frac{X_i - t}{h_n}\right) dt + o(n^{-1/2}) \text{ a.s.} \\ &:= Q_1(\widehat{g}_y) + Q_2(\widehat{g}_y) + o(n^{-1/2}) \text{ a.s.} \end{aligned}$$

Because of conditions (A.7)-(A.10) for $\widehat{g}'_y$ and $\mathcal{G}'$, we can use (A.5) to write $Q_2(\widehat{g}_y)$ as

$$Q_2(\widehat{g}_y) = \frac{1}{n} \sum_{i=1}^n \widehat{g}_y(X_i, V_i) \frac{f_X(X_i) - \widehat{f}_X(X_i)}{\widehat{f}_X(X_i)} + o_P(n^{-1/2}).$$

By Corollary 2.3.12 in the book of [25] we have

$$\lim_{\alpha \downarrow 0} \limsup_{n \rightarrow \infty} P \left(\sup_{g' \in \mathcal{G}', \text{Var}(g') < \alpha} n^{-1/2} \left| \sum_{i=1}^n g'(X_i, V_i) - E(g'(X, V)) \right| > \varepsilon \right) = 0, \quad (\text{A.11})$$

for every $\varepsilon > 0$. Since, $\lim_{n \rightarrow \infty} P(\widehat{g}_y \frac{\widehat{f}_X - \widehat{f}_X}{\widehat{f}_X} \in \mathcal{G}') = 1$ and $\text{Var}(\widehat{g}_y \frac{\widehat{f}_X - \widehat{f}_X}{\widehat{f}_X}) = o(1)$, we can use (A.11) to approximate $Q_2(\widehat{g}_y)$ with the corresponding expectation:

$$\begin{aligned} Q_2(\widehat{g}_y) &= E \left[\widehat{g}_y(X, V) \frac{\widehat{f}_X(X) - \widehat{f}_X(X)}{\widehat{f}_X(X)} \middle| \mathcal{X}_n \right] + o_P(n^{-1/2}) \\ &= E \left[E[\widehat{g}_y(X, V) | X, \mathcal{X}_n] \frac{\widehat{f}_X(X) - \widehat{f}_X(X)}{\widehat{f}_X(X)} \middle| \mathcal{X}_n \right] + o_P(n^{-1/2}) \\ &= o_P(n^{-1/2}). \end{aligned}$$

To obtain the last equality we used that $\|\widehat{f}_X - \widehat{f}_X\|_\infty = O((nh_n)^{-1/2}(\log n)^{1/2})$ a.s. and $\sup_{x \in R_X} |E[\widehat{g}_y(X, V) | X = x, \mathcal{X}_n]| = O((nh_n)^{-1/2}(\log n)^{1/2})$ a.s. (see Proposition 3.5 in [22]). Now, applying (A.5) on $Q_1(\widehat{g}_y)$ we get

$$Q(\widehat{g}_y) = \frac{1}{n} \sum_{i=1}^n \widehat{g}_y(X_i, V_i) + o_P(n^{-1/2}),$$

which concludes the proof.

Now, it remains to show that conditions (A.7), (A.8), (A.9) and (A.10) are satisfied (proving the corresponding conditions for $\widehat{g}_y$ and $\mathcal{G}'$ will be omitted since it uses the same techniques and reasoning). Condition (A.7) is easily verified, while condition (A.8) follows from Propositions 3.5, 3.6 and 3.7 in [22]. Because of condition (A.7) we can bound the expectation in condition (A.9) by

$$C \sup_{u \in [-a, a]} E|g(X + uh_n, V) - g(X, V)|.$$

Now, we decompose the function g as $g(X, V) = I(X \in B_y)z(X, V)$ and write

$$\begin{aligned} Q_g(uh_n) &= E|E[g(X + uh_n, V) | X] - E[g(X, V) | X]| \\ &= E|I(X + uh_n \in B_y)E[z(X + uh_n, V) | X] - I(X \in B_y)E[z(X, V) | X]|. \end{aligned}$$

By using assumptions (A4) and (A5)(iv,vi), it is easy to see that the function $(x, e) \mapsto E[z(x + e, V) | X = x]$ has uniformly bounded partial derivative over e , for e small enough. This allows us to use a Taylor expansion and to obtain

$$\begin{aligned} Q_g(uh_n) &= E \left\{ |I(X + uh_n \in B_y) - I(X \in B_y)| |E[z(X, V) | X]| \right\} + O(uh_n) \\ &\leq C \int_{R_X} |I(x + uh_n \in B_y) - I(x \in B_y)| dx + O(uh_n) \\ &= C \int_{R_X} I(x \in B_y \Delta \{B_y - uh_n\}) dx + O(uh_n) \\ &\leq C \sum_{i=1}^k \int_{\sup B_{yi} - uh_n}^{\sup B_{yi} + uh_n} dx + C \sum_{i=1}^k \int_{\inf B_{yi} - uh_n}^{\inf B_{yi} + uh_n} dx + O(uh_n) \\ &= O(uh_n), \end{aligned}$$

where Δ is the symmetric difference, $B_y = \bigcup_{i=1}^k B_{yi}$, the sets B_{yi} are convex and $k \leq \lambda(R_X)/\beta < \infty$ (for the definition of β see Section 2). This implies condition (A.9). To prove condition (A.10), we use the notation $E[\cdot] = E[\cdot | \mathcal{X}_n]$ and write the expectation in condition (A.10) as

$$\int E \left[\widehat{g}_y(X + uh_n, V) - \widehat{g}_y(X, V) \right] K(u) du.$$

Using the decomposition $\widehat{g}_y(x, v) = I(x \in B_y)\widehat{z}_y(x, v)$, we can write the expectation in the integral above as

$$\begin{aligned} Q_{\widehat{g}_y}(uh_n) &= E \left\{ I(X + uh_n \in B_y) \left[E[\widehat{z}_y(X + uh_n, V)|X] - E[\widehat{z}_y(X, V)|X] \right] \right\} \\ &\quad + E \left\{ \left[I(X + uh_n \in B_y) - I(X \in B_y) \right] E[\widehat{z}_y(X, V)|X] \right\} \\ &:= Q_{\widehat{g}_y,1}(uh_n) + Q_{\widehat{g}_y,2}(uh_n). \end{aligned}$$

In order to bound the second term on the right hand side, we use similar calculations as when dealing with $Q_g(uh_n)$ to get

$$\begin{aligned} |Q_{\widehat{g}_y,2}(uh_n)| &\leq C \sum_{i=1}^k \int_{\sup B_{y_i} - uh_n}^{\sup B_{y_i} + uh_n} |E[\widehat{z}_y(x, V)|X = x]| dx + C \sum_{i=1}^k \int_{\inf B_{y_i} - uh_n}^{\inf B_{y_i} + uh_n} |E[\widehat{z}_y(x, V)|X = x]| dx \\ &\leq 2Ck \sup_{y \leq \tau_\eta} \sup_{d(x, B_y) \leq uh_n} |E[\widehat{z}_y(x, V)|X = x]| uh_n \\ &= O\left((nh_n)^{-1/2}(\log n)^{1/2}h_n\right) = o(n^{-1/2}) \text{ a.s.}, \end{aligned}$$

uniformly in $y \leq \tau_\delta$ and $u \in [-a, a]$, where $d(x, B_y) = \inf\{|x - x_1| : x_1 \in B_y\}$. To get the first equality we used Proposition 3.5 in [22], and assumptions (A4) and (A5)(iv,vi). The term $Q_{\widehat{g}_y,1}(uh_n)$ can be bounded as follows:

$$\begin{aligned} |Q_{\widehat{g}_y,1}(uh_n)| &\leq \sup_{y \leq \tau_\eta} \sup_{d(x, B_y) \leq uh_n} \left| E \left[\frac{\partial}{\partial x} E[\widehat{z}_y(x, V)|X = x] \right] uh_n \right| \\ &= O\left((nh_n)^{-1/2}(\log n)^{1/2}h_n\right) = o(n^{-1/2}) \text{ a.s.} \end{aligned}$$

uniformly in $y \leq \tau_\delta$ and $u \in [-a, a]$. To get the first equality we used again Proposition 3.5 in [22], and assumptions (A4) and (A5)(iv,vi). This implies (A.10). $\square$

Appendix B.

This section contains results on uniform convergence rates of quantities needed for showing that the remainder terms in (15) of Theorem 1 are $o(n^{-1/2})$ a.s.

Lemma 6. Assume (A1)(i,ii) and (A4). Then, for $\alpha \in (0, 1]$ and $0 < M < \infty$,

$$\sup_{v \in [\alpha, 1], y \leq \tau_\eta} |\widehat{\phi}_{(y)}(v) - \phi_{(y)}(v)| = O(n^{-1/3}(\log n)^{1/2}) \text{ a.s.}, \quad (\text{B.1})$$

$$\sup_{v \in [\alpha, 1], y \leq \tau_\eta} |\widehat{\phi}'_{(y)}(v) - \phi'_{(y)}(v)| = O(n^{-1/3}(\log n)^{1/2}) \text{ a.s.}, \quad (\text{B.2})$$

$$\sup_{v \in [\alpha, 1], y \leq \tau_\eta} |\widehat{\phi}''_{(y)}(v) - \phi''_{(y)}(v)| = O(n^{-1/3}(\log n)^{1/2}) \text{ a.s.}, \quad (\text{B.3})$$

and

$$\sup_{u \in [0, M], y \leq \tau_\eta} |\widehat{\phi}_{(y)}^{-1}(u) - \phi_{(y)}^{-1}(u)| = O(n^{-1/3}(\log n)^{1/2}) \text{ a.s.} \quad (\text{B.4})$$

Proof. Statements (B.1), (B.2) and (B.3) can be proven in an analogous way. Therefore, we will prove only statement (B.3). We can write

$$\widehat{\phi}''_{(y)}(v) - \phi''_{(y)}(v) = \int_{B_y} \phi''_x(v) d[\widehat{F}_X(x) - F_X(x)].$$

Now, since $\phi''_x(v)$ and $\phi'''_x(v)$ are uniformly bounded in $(v, x) \in [\alpha, 1] \times R_X$, we can easily show by following calculations done for proving (B.5) in Lemma 7 below, that statement (B.3) is true. To prove statement (B.4) we use a first order Taylor expansion to get

$$\widehat{\phi}_{(y)}^{-1}(u) - \phi_{(y)}^{-1}(u) = \frac{-1}{\widehat{\phi}'_{(y)}(\xi(u, y))} \left[\widehat{\phi}_{(y)}(\phi_{(y)}^{-1}(u)) - \widehat{\phi}_{(y)}(\widehat{\phi}_{(y)}^{-1}(u)) \right],$$

where $\xi(u, y)$ is between $\widehat{\phi}_{(y)}^{-1}(u)$ and $\phi_{(y)}^{-1}(u)$. The second factor on the right hand side is $O(n^{-1/3}(\log n)^{1/2})$ a.s. by (B.1). The first factor on the right hand side is a.s. uniformly bounded (in $u \in [0, M]$ and $y \leq \tau_\eta$) because of assumption (A4)(iii). $\square$

When showing the negligibility of the remainder terms in the proof of Theorem 1 via Lemma 7 below, we need to verify certain assumptions regarding the rate of $G_n(y, x)$ and $\frac{\partial}{\partial x} G_n(y, x)$, where $G_n(y, x)$ is a stochastic process. This will either be trivial or will reduce to verifying that $\sup_{y,x} |\widehat{L}(y|x) - L(y|x)| = O((nh_n)^{-1/2}(\log n)^{1/2})$ a.s., $\sup_{y,x} |\widehat{\dot{L}}(y|x) - \dot{L}(y|x)| = O(1)$ a.s. or $\sup_{y,x} |\widehat{\dot{L}}(y|x) - \dot{L}(y|x)| = O((nh_n^3)^{-1/2}(\log n)^{1/2})$ a.s., for $L \in \{H_e, H_e^u\}$, which is true by Lemma 9.

Lemma 7. Assume (A1)(i,ii). Let $G_n(y, x)$ be a stochastic process that is satisfying $\sup_{y \leq \tau_\eta} \sup_{x \in B_y} \{|G_n(y, x)|, |\frac{\partial}{\partial x} G_n(y, x)|\} = O(1)$ a.s. Then,

$$\sup_{y \leq \tau_\eta} \left| \int_{B_y} G_n(y, x) d[\widehat{F}_X(x) - F_X(x)] \right| = O(n^{-1/3}(\log n)^{1/2}) \text{ a.s.} \quad (\text{B.5})$$

If in addition we assume that $\sup_{y \leq \tau_\eta} \sup_{x \in B_y} |G_n(y, x)| = O((nh_n)^{-1/2}(\log n)^{1/2})$ a.s. and $\sup_{y \leq \tau_\eta} \sup_{x \in B_y} |\frac{\partial}{\partial x} G_n(y, x)| = O((nh_n^3)^{-1/2}(\log n)^{1/2})$ a.s., then

$$\sup_{y \leq \tau_\eta} \left| \int_{B_y} G_n(y, x) d[\widehat{F}_X(x) - F_X(x)] \right| = o(n^{-1/2}) \text{ a.s.} \quad (\text{B.6})$$

Proof. We start by partitioning $R_X = [a, b]$ using a grid $a = x_1 < x_2 < \dots < x_m = b$ such that $x_{i+1} - x_i < a_n$, $i = 1, \dots, m-1$, where $m = C a_n^{-1}$ and a_n is a sequence of constants to be specified further on. We can then write

$$\begin{aligned} & \left| \int_{B_y} G_n(y, x) d[\widehat{F}_X(x) - F_X(x)] \right| \\ &= \left| \sum_{\substack{i=1 \\ x_i \in B_y}}^{m-1} G_n(y, x_i) \int_{B_y \cap [x_i, x_{i+1}]} d[\widehat{F}_X(x) - F_X(x)] \right. \\ & \quad \left. + \sum_{\substack{i=1 \\ x_i \in B_y}}^{m-1} \int_{B_y \cap [x_i, x_{i+1}]} [G_n(y, x) - G_n(y, x_i)] d[\widehat{F}_X(x) - F_X(x)] \right| \\ &\leq C a_n^{-1} \sup_{y \leq \tau_\eta} \sup_{x \in B_y} |G_n(y, x)| \times \sup_{|x-x'| < a_n} |\widehat{F}_X(x') - F_X(x') - \widehat{F}_X(x) + F_X(x)| + 2k \sup_{y \leq \tau_\eta} \sup_{x \in B_y} \left| \frac{\partial}{\partial x} G_n(y, x) \right| a_n, \end{aligned}$$

where the equality holds for n big enough, and $k \leq \lfloor \lambda(R_X)/\beta \rfloor$. Under the assumption that $\frac{\partial}{\partial x} G_n(y, x)$ is a.s. uniformly bounded, by defining $a_n = n^{-1/3}$, the second term on the right hand side is of the order $O(a_n) = O(n^{-1/3})$ a.s. By using Theorem 0.2 in [28] we can bound the first term by $a_n^{-1} O(n^{-1/2} a_n^{1/2} (\log n)^{1/2}) = O(n^{-1/3}(\log n)^{1/2})$ a.s. This proves (B.5).

By taking now $a_n = n^{-1/2}$, statement (B.6) is true, because under the additional assumptions for (B.6), the second term above is $a_n O(n^{-1/2} h_n^{-3/2} (\log n)^{1/2}) = o(n^{-1/2})$ a.s. Again by using Theorem 0.2 in [28] we can bound the first term above by $a_n^{-1} O((nh_n)^{-1/2} (\log n)^{1/2}) \times O(n^{-1/2} a_n^{1/2} (\log n)^{1/2}) = o(n^{-1/2})$ a.s. $\square$

Lemma 8. Under the conditions of Theorem 1 we have

$$\sup_{y \leq \tau_\eta} |U_n(y) - U(y)| = O\left((nh_n)^{-1/2}(\log n)^{1/2}\right) \text{ a.s.}, \quad (\text{B.7})$$

$$\sup_{y \leq \tau_\eta} |\widetilde{U}_n(y) - U(y)| = O\left(n^{-1/3}(\log n)^{1/2}\right) \text{ a.s.}, \quad (\text{B.8})$$

where $U(y)$, $U_n(y)$ and $\widetilde{U}_n(y)$ are defined in (11)

Proof. To deal with (B.7) we calculate

$$\begin{aligned} U_n(y) - U(y) &= - \int_{B_y} \int_{-\infty}^y \phi'_x \left(\widehat{H}_e(s|x) \right) d \left[\widehat{H}_e^u(s|x) - H_e^u(s|x) \right] dF_X(x) \\ &\quad + \int_{B_y} \int_{-\infty}^y \left[\phi'_x \left(\overline{H}_e(s|x) \right) - \phi'_x \left(\widehat{H}_e(s|x) \right) \right] dH_e^u(s|x) dF_X(x). \end{aligned}$$

Now, by using integration by parts for the first term, and a first order Taylor expansion for the second term we get

$$\begin{aligned} U_n(y) - U(y) &= - \int_{B_y} \phi'_x \left(\widehat{H}_e(y|x) \right) \left[\widehat{H}_e^u(y|x) - H_e^u(y|x) \right] dF_X(x) \\ &\quad + \int_{B_y} \int_{-\infty}^y \phi''_x \left(\widehat{H}_e(s|x) \right) \left[\widehat{H}_e^u(s|x) - H_e^u(s|x) \right] d\widehat{H}_e(s|x) dF_X(x) \\ &\quad - \int_{B_y} \int_{-\infty}^y \phi''_x \left(\overline{H}_e(s|x) \right) \left[\widehat{H}_e(s|x) - \overline{H}_e(s|x) \right] dH_e^u(s|x) dF_X(x) \\ &\quad + \frac{1}{2} \int_{B_y} \int_{-\infty}^y \phi'''_x \left(\xi(s, x) \right) \left[\widehat{H}_e(s|x) - \overline{H}_e(s|x) \right]^2 dH_e^u(s|x) dF_X(x), \end{aligned}$$

where $\xi(s, x)$ is between $\overline{H}_e(s|x)$ and $\widehat{H}_e(s|x)$. Now, by using assumption (A4) and Lemma 9 below we get the desired order.

Statement (B.8) can be bounded by $\sup_{y \leq \tau_\eta} |\widetilde{U}_n(y) - U_n(y)| + \sup_{y \leq \tau_\eta} |U_n(y) - U(y)|$. The first term is of the order $O\left(n^{-1/3}(\log n)^{1/2}\right)$ a.s. by Lemma 7, while the second term is $O\left((nh_n)^{-1/2}(\log n)^{1/2}\right)$ a.s. by (B.7). This concludes the proof. $\square$

The following lemma is a generalization of Lemma 4.1 in [1] regarding the uniform (in $y \in \mathbf{R}$ and $x \in R_{X,n}$) rate of convergence of the difference $\widehat{H}(y|x) - H(y|x)$ to the uniform rate of convergence of $\widehat{H}_e(y|x) - H_e(y|x)$. The former difference is a sum of i.i.d. random variables, while the latter difference is a sum of non-independent random variables.

Lemma 9. Assume (A1)-(A3), and assume that (A5)(i,ii,iv,v) holds for $H_e(y|x)$ and $H_e^u(y|x)$. Then,

- (i) $\sup_{x \in R_{X,n}} \sup_{y \in \mathbf{R}} \left| \widehat{H}_e(y|x) - H_e(y|x) \right| = O((nh_n)^{-1/2}(\log n)^{1/2}) \text{ a.s.}$
- (ii) $\sup_{x \in R_{X,n}} \sup_{y \in \mathbf{R}} \left| \dot{\widehat{H}}_e(y|x) - \dot{H}_e(y|x) \right| = O((nh_n^3)^{-1/2}(\log n)^{1/2}) \text{ a.s.}$
- (iii) $\sup_{x \in R_{X,n}} \sup_{y \in \mathbf{R}} \left| \widehat{H}_e^u(y|x) - H_e^u(y|x) \right| = O((nh_n)^{-1/2}(\log n)^{1/2}) \text{ a.s.}$
- (iv) $\sup_{x \in R_{X,n}} \sup_{y \in \mathbf{R}} \left| \dot{\widehat{H}}_e^u(y|x) - \dot{H}_e^u(y|x) \right| = O((nh_n^3)^{-1/2}(\log n)^{1/2}) \text{ a.s.}$

where $R_{X,n} = \{x \in R_X, \|x - \partial R_X\| > 2ah_n\}$.

Proof. The proofs of statements (i), (ii), (iii) and (iv) use the same idea so we will only show (i). For that we define a new estimator

$$\widehat{H}_e^*(y|x) = \sum_{i=1}^n W_{ni}(x, h_n) I(E_i \leq y),$$

for which statement (i) is true by Lemma 4.1 in [1]. To finish the proof we will show that the difference between $\widehat{H}_e$ and $\widehat{H}_e^*$ is uniformly of the order $O((nh_n)^{-1/2}(\log n)^{1/2})$ a.s. Consider

$$\begin{aligned} \left| \widehat{H}_e(y|x) - \widehat{H}_e^*(y|x) \right| &= \left| \sum_{i=1}^n W_{ni}(x, h_n) \left[I(\widehat{E}_i \leq y) - I(E_i \leq y) \right] \right| \\ &= \left| \sum_{i=1}^n W_{ni}(x, h_n) \left[I\left(E_i \leq y \frac{\widehat{\sigma}(X_i)}{\sigma(X_i)} + \frac{\widehat{m}(X_i) - m(X_i)}{\sigma(X_i)}\right) - I(E_i \leq y) \right] \right| \\ &\leq \sum_{i=1}^n W_{ni}(x, h_n) \left[I(E_i \leq y + |y|\beta_n + \alpha_n) - I(E_i \leq y - |y|\beta_n - \alpha_n) \right] \\ &= \widehat{H}_e^*(y + |y|\beta_n + \alpha_n|x) - \widehat{H}_e^*(y - |y|\beta_n - \alpha_n|x), \end{aligned}$$

where $\alpha_n = \sup_{x \in R_{X,n}} |\widehat{m}(x) - m(x)|/\sigma(x)$ and $\beta_n = \sup_{x \in R_{X,n}} |\widehat{\sigma}(x) - \sigma(x)|/\sigma(x)$. Now, by adding and subtracting $H_e(y + |y|\beta_n + \alpha_n|x) - H_e(y - |y|\beta_n - \alpha_n|x)$, we get

$$\begin{aligned} \sup_{y \in R, x \in R_{X,n}} \left| \widehat{H}_e(y|x) - \widehat{H}_e^*(y|x) \right| &\leq \sup_{y \in R, x \in R_{X,n}} \left| \widehat{H}_e^*(y + |y|\beta_n + \alpha_n|x) - H_e(y + |y|\beta_n + \alpha_n|x) \right| \\ &\quad + \sup_{y \in R, x \in R_{X,n}} \left| \widehat{H}_e^*(y - |y|\beta_n - \alpha_n|x) - H_e(y - |y|\beta_n - \alpha_n|x) \right| \\ &\quad + \sup_{y \in R, x \in R_X} |H_e(y + |y|\beta_n + \alpha_n|x) - H_e(y - |y|\beta_n - \alpha_n|x)| \\ &= 2 \sup_{y \in R, x \in R_{X,n}} \left| \widehat{H}_e^*(y|x) - H_e(y|x) \right| \\ &\quad + \sup_{y \in R, x \in R_X} |h_e(\xi_{x,y}|x) [2\beta_n|y| + 2\alpha_n]|, \end{aligned}$$

where $\xi_{x,y}$ is between $y - |y|\beta_n - \alpha_n$ and $y + |y|\beta_n + \alpha_n$. As explained in the beginning the first term on the right hand side is of the order $O((nh_n)^{-1/2}(\log n)^{1/2})$ a.s. The second term is of the same order because $\sup_{y \in R, x \in R_X} |h_e(y|x)y| < \infty$ by assumption (A5)(ii) and because α_n and β_n are $O((nh_n)^{-1/2}(\log n)^{1/2})$ a.s. by Proposition 3.5 in [22]. $\square$

Lemma 10. Under the assumptions of Theorem 1 we have

$$\begin{aligned} \sup_{y \leq \tau_\eta} \sup_{x \in B_y} \int_{-\infty}^y \left[\phi'_x(\widehat{H}_e(s|x)) - \phi'_x(\overline{H}_e(s|x)) \right] d \left[\widehat{H}_e^u(s|x) - H_e^u(s|x) \right] \\ = O((nh_n)^{-3/4}(\log n)^{3/4+\alpha}) \text{ a.s.}, \end{aligned} \quad (\text{B.9})$$

where $\alpha > 0$ is an arbitrarily small constant.

Proof. The proof is very analogous to the proof of Lemma A.1 in [22]. The only difference is that we use Lemma 11 below for the uniform rate of convergence of the modulus of continuity $\widehat{H}_e(y_1|x) - \widehat{H}_e(y_2|x) - H_e(y_1|x) + H_e(y_2|x)$, whereas they use Lemma 4.4 in [7] for $\widehat{H}(y_1|x) - \widehat{H}(y_2|x) - H(y_1|x) + H(y_2|x)$. Details of the proof are omitted and can be found in Lemma A.1 in [22]. $\square$

The following lemma is a uniform modulus of continuity result for the Nadaraya-Watson type estimator $\widehat{H}_e(y|x)$. It is an adaptation of Lemma 4.4 in [7]. A major difficulty in this adaptation is that $\widehat{H}_e(y|x)$ is not a sum of independent random variables.

Lemma 11. Assume (A1)-(A4), and assume that (A5) and (A6) hold for $H_e(y|x)$. Let $a_n = O((nh_n)^{-1/2}(\log n)^{1/2})$. Then,

$$\begin{aligned} \sup_{x \in R_{X,n}} \sup_{(y_1, y_2) \in J_{a_n}} & | \widehat{H}_e(y_1|x) - \widehat{H}_e(y_2|x) - H_e(y_1|x) + H_e(y_2|x) | \\ &= O\left(a_n^{1/2}(nh_n)^{-1/2}(\log n)^{1/2+\alpha} + a_n^2 + a_n h_n\right) = o\left(n^{-1/2}\right) \text{ a.s.}, \end{aligned} \quad (\text{B.10})$$

for an arbitrarily small constant $\alpha > 0$, $J_{a_n} = \{(y_1, y_2) : |M(y_1) - M(y_2)| \leq a_n\}$ and $M(y) = \sum_{i=1}^4 M_i(y)$ (see (A6) for $L = H_e$).

Proof. In this proof we will use an index $(-r)$ to denote estimators that leave out the random variables E_r and Δ_r :

$$\begin{aligned} \widehat{H}_{(-r)}(y|x) &:= \sum_{i=1, i \neq r}^n W_{ni}(x, h_n) I(T_i \leq y), \\ \widetilde{F}_{(-r)}(y|x) &:= \phi_x^{-1} \left\{ - \sum_{T_i \leq y, \Delta_i = 1, i \neq r} \left[\phi_x \left(\widehat{H}_{(-r)}(T_i^-|x) \right) - \phi_x \left(\widehat{H}_{(-r)}(T_i|x) \right) \right] \right\}, \\ \widehat{m}_{(-r)}(x) &:= \sum_{i=1, i \neq r}^n \Delta \widetilde{F}_{(-r)}(T_i|x) T_i J(\widetilde{F}_{(-r)}(T_i|x)), \end{aligned}$$

and

$$\widehat{\sigma}_{(-r)}^2(x) := \sum_{i=1, i \neq r}^n \Delta \widetilde{F}_{(-r)}(T_i|x) T_i^2 J(\widetilde{F}_{(-r)}(T_i|x)) - \widehat{m}_{(-r)}^2(x).$$

We will also use the notation $\Delta(y, x) = y\Delta_2(x) + \Delta_1(x)$, where $\Delta_2(x) = \frac{\widehat{\sigma}(x) - \sigma(x)}{\sigma(x)}$ and $\Delta_1(x) = \frac{\widehat{m}(x) - m(x)}{\sigma(x)}$. Further we will denote $\Delta_{(-r)}$, $\Delta_{1(-r)}$ and $\Delta_{2(-r)}$ when replacing $\widehat{m}$ and $\widehat{\sigma}$ by $\widehat{m}_{(-r)}$ and $\widehat{\sigma}_{(-r)}$ in the functions Δ , Δ_1 and Δ_2 , respectively.

We will prove the main statement of the Lemma by showing the following two statements:

$$\begin{aligned} \sup_{x \in R_{X,n}} \sup_{(y_1, y_2) \in J_{a_n}} & | \widehat{H}_e(y_1|x) - \widehat{H}_e(y_2|x) - \widetilde{H}_e(y_1|x) + \widetilde{H}_e(y_2|x) | \\ &= O(a_n^{1/2}(nh_n)^{-1/2}(\log n)^{1/2+\alpha}) \text{ a.s.}, \end{aligned} \quad (\text{B.11})$$

$$\begin{aligned} \sup_{x \in R_{X,n}} \sup_{(y_1, y_2) \in J_{a_n}} & | \widetilde{H}_e(y_1|x) - \widetilde{H}_e(y_2|x) - H_e(y_1|x) + H_e(y_2|x) | \\ &= O(a_n^2 + a_n h_n) \text{ a.s.}, \end{aligned} \quad (\text{B.12})$$

where $\widetilde{H}_e(y|x) = \sum_{r=1}^n W_{nr}(x, h_n) H_e(y + \Delta_{(-r)}(y, X_r)|X_r)$. To show (B.12) we calculate, for all y_1 and y_2 such that $|(M_2 + M_3 + M_4)(y_1) - (M_2 + M_3 + M_4)(y_2)| < a_n$, the following:

$$\begin{aligned} & \widetilde{H}_e(y_1|x) - \widetilde{H}_e(y_2|x) - H_e(y_1|x) + H_e(y_2|x) \\ &= \sum_{r=1}^n W_{nr}(x, h_n) \left\{ H_e(y_1 + \Delta_{(-r)}(y_1, X_r)|X_r) - H_e(y_2 + \Delta_{(-r)}(y_2, X_r)|X_r) - H_e(y_1|x) + H_e(y_2|x) \right\} \\ &= \sum_{r=1}^n W_{nr}(x, h_n) \left\{ H'_e(y_1|X_r) \Delta_{(-r)}(y_1, X_r) - H'_e(y_2|X_r) \Delta_{(-r)}(y_2, X_r) \right. \\ & \quad \left. + \frac{1}{2} H''_e(\xi_{1r}|X_r) \Delta_{(-r)}^2(y_1, X_r) - \frac{1}{2} H''_e(\xi_{2r}|X_r) \Delta_{(-r)}^2(y_2, X_r) \right. \\ & \quad \left. + [\dot{H}_e(y_1|x'_r) - \dot{H}_e(y_2|x'_r)](X_r - x) \right\} \\ &= O(a_n^2 + a_n^2 + a_n h_n) \text{ a.s.}, \end{aligned}$$

where x'_r is between x and X_r , ξ_{ir} is between y_i and $y_i + \Delta_{(-r)}(y_i, X_r)$ for $i = 1, 2$ and $r = 1, \dots, n$. In the last equality we used assumptions (A5)(ii,iii), Proposition 3.5 in [22], and the fact that $\sup_{x \in R_{X,n}} \max_{r=1, \dots, n} |W_{nr}(x, h_n)| = O((nh_n)^{-1})$ a.s., which is easy to show.

To prove (B.11) we start by partitioning R into $m_n = \lfloor M(+\infty)/a_n \rfloor$ subintervals $-\infty = y_0 < y_1 < \dots < y_{m_n} = \infty$, such that $M(y_{i+1}) - M(y_i) = \bar{a}_n := M(+\infty)/m_n$. For each $i = 1, \dots, m_n - 1$ define $I_{ni} = [y_{i-1}, y_{i+1}]$. Further partition each interval I_{ni} into $2b_n$ smaller intervals $[y_{ij}, y_{i,j+1}]$ for $j = -b_n, -b_n + 1, \dots, b_n$, where $b_n = O(a_n^{1/2}(nh_n)^{1/2}(\log n)^{-1/2})$, such that $M(y_{i,j+1}) - M(y_{ij}) = \frac{\bar{a}_n}{b_n}$. It can be easily verified that $a_n \leq \bar{a}_n \leq 2a_n$ for n large enough, and for any $y_1, y_2 \in R$ with $|M(y_1) - M(y_2)| < a_n$, there exists an interval I_{ni} such that $y_1, y_2 \in I_{ni}$. Hence, by using the monotonicity of $\widehat{H}_e(\cdot|x)$, it can be seen that (B.11) is bounded by

$$\sup_{x \in R_{X,n}} \max_{1 \leq i \leq m_n - 1} \max_{-b_n \leq j, k \leq b_n} |\widehat{H}_e(y_{ik}|x) - \widehat{H}_e(y_{ij}|x) - \widetilde{H}_e(y_{ik}|x) + \widetilde{H}_e(y_{ij}|x)| \quad (\text{B.13})$$

$$+ 2 \sup_{x \in R_{X,n}} \sup\{|\widetilde{H}_e(y_1|x) - \widetilde{H}_e(y_2|x)| : |M(y_1) - M(y_2)| \leq \bar{a}_n/b_n\}. \quad (\text{B.14})$$

We can write the term between absolute values in (B.14) as

$$\begin{aligned} & \sum_{r=1}^n W_{nr}(x, h_n) \left\{ H_e(y_1 + \Delta_{(-r)}(y_1, X_r)|X_r) - H_e(y_2 + \Delta_{(-r)}(y_2, X_r)|X_r) \right\} \\ &= \sum_{r=1}^n W_{nr}(x, h_n) \left\{ H_e(y_1|X_r) - H_e(y_2|X_r) \right. \\ & \quad + H'_e(y_1|X_r)\Delta_{(-r)}(y_1, X_r) - H'_e(y_2|X_r)\Delta_{(-r)}(y_2, X_r) \\ & \quad \left. + \frac{1}{2}H''_e(\xi_{1r}|X_r)\Delta_{(-r)}^2(y_1, X_r) - \frac{1}{2}H''_e(\xi_{2r}|X_r)\Delta_{(-r)}^2(y_2, X_r) \right\}, \end{aligned}$$

where ξ_{ir} is between y_i and $y_i + \Delta_{(-r)}(y_i, X_r)$ for $i = 1, 2$. The first difference on the right hand side is of the order $\frac{a_n}{b_n} = O(a_n^{1/2}(nh_n)^{-1/2}(\log n)^{1/2})$. The third difference is of the order $O((nh_n)^{-1} \log n)$ a.s., because of assumption (A5)(iii), and because the terms $\Delta_{1(-r)}(y_i, X_r)$ and $\Delta_{2(-r)}(y_i, X_r)$ are uniformly $O((nh_n)^{-1/2}(\log n)^{1/2})$ a.s. (by Proposition 3.5 in [22], and the relation $\sup_{x \in R_{X,n}} \max_{r=1, \dots, n} |W_{nr}(x, h_n)| = O((nh_n)^{-1})$ a.s.). To show that the second difference is negligible we calculate

$$\begin{aligned} & |[H'_e(y_1|X_r)y_1 - H'_e(y_2|X_r)y_2]\Delta_{2(-r)}(X_r) + [H'_e(y_1|X_r) - H'_e(y_2|X_r)]\Delta_{1(-r)}(X_r)| \\ & \leq |M(y_1) - M(y_2)| |\Delta_{2(-r)}(X_r)| + |M(y_1) - M(y_2)| |\Delta_{1(-r)}(X_r)| \\ & = O\left(\frac{a_n}{b_n}(nh_n)^{-1/2}(\log n)^{1/2}\right) a.s. \end{aligned}$$

Hence, we showed that (B.14) is $O(a_n^{1/2}(nh_n)^{-1/2}(\log n)^{1/2})$ a.s.

To deal with (B.13) we define the grid $a = x_0 < x_1 < \dots < x_{k_n} = b$ of $R_X = [a, b]$ such that $x_i - x_{i-1} \leq a_n^{1/2}(nh_n)^{-1/2}(\log n)^{1/2}h_n^3$, $i = 1, \dots, k_n$. By similar calculations as in Lemma 4.2 in [7], we have uniformly, up to a remainder term of order $O(a_n^{1/2}(nh_n)^{-1/2}(\log n)^{1/2})$ a.s., that (B.13) is bounded by

$$A_n := \max_{l=1, \dots, k_n} \max_{1 \leq i \leq m_n - 1} \max_{-b_n \leq j, k \leq b_n} |\widehat{H}_e(y_{ik}|x_l) - \widehat{H}_e(y_{ij}|x_l) - \widetilde{H}_e(y_{ik}|x_l) + \widetilde{H}_e(y_{ij}|x_l)|.$$

Before continuing we define D_n as a set where for a fixed constant $0 < C' < \infty$ the following conditions are satisfied:

$$\sup_{x \in R_{X,n}} \max_{r=1, \dots, n} |W_{nr}(x, h_n)| \leq C'(nh_n)^{-1}(\log n)^\alpha, \quad (\text{B.15})$$

$$\sup_{x \in R_{X,n}} \max_{r=1, \dots, n} \max_{i=1, 2} |\Delta_{i(-r)}(x)| \leq C'(nh_n)^{-1/2}(\log n)^{1/2+\alpha}, \quad (\text{B.16})$$

and

$$\sup_{x \in R_{X,n}} \max_{r=1, \dots, n} \max_{i=1, 2} |\Delta_{i(-r)}(x) - \Delta_i(x)| \leq C'(nh_n)^{-1}(\log n)^\alpha. \quad (\text{B.17})$$

We can show that $P(\cup_{m=1}^{\infty} \cap_{n=m}^{\infty} D_n) = 1$. Indeed, as mentioned before we have that $\sup_{x \in R_{X_n}} \max_{r=1, \dots, n} |W_{nr}(x, h_n)| = O((nh_n)^{-1})$ a.s. By additionally using Proposition 3.5 in [22], we have that the term on the left hand side in (B.16) is $O((nh_n)^{-1})$ a.s. Proving that the term on the left hand side in (B.17) is $O((nh_n)^{-1} \log n)$ a.s. is a straightforward but tedious calculation and is omitted. On the set D_n , we can write $\tilde{H}_e(y_{ik}|x) - \tilde{H}_e(y_{ij}|x) - \tilde{H}_e(y_{ik}|x_l) + \tilde{H}_e(y_{ij}|x_l) = \sum_{r=1}^n X_{rijkl}$, where

$$X_{rijkl} = \tilde{W}_{nr}(x_l, h_n) \left\{ I(E_r \leq y_{ik} + \tilde{\Delta}_{(-r)}(y_{ik}, X_r)) - I(E_r \leq y_{ij} + \tilde{\Delta}_{(-r)}(y_{ij}, X_r)) + \tilde{Z}_{rijkl} \right. \\ \left. - H_e(y_{ik} + \tilde{\Delta}_{(-r)}(y_{ik}, X_r)|X_r) + H_e(y_{ij} + \tilde{\Delta}_{(-r)}(y_{ij}, X_r)|X_r) \right\},$$

$Z_r(y) := I(E_r \leq y + \Delta(y, X_r)) - I(E_r \leq y + \Delta_{(-r)}(y, X_r))$, $\tilde{Z}_{rijk} = [Z_r(y_{ik}) - Z_r(y_{ij})]I_{D_n}$, $\tilde{W}_{nr}(x, h_n) = W_{nr}(x, h_n)I_{D_n}$, $\tilde{\Delta}_{(-r)}(y, x) = y\tilde{\Delta}_{2(-r)}(x) + \tilde{\Delta}_{1(-r)}(x)$ and $\tilde{\Delta}_{i(-r)}(x) = \Delta_{i(-r)}(x) \times I_{D_n}$, $i = 1, 2$. We define a (centered) version of the random variable X_{rijkl} by $\tilde{X}_{rijkl} = X_{rijkl} - E[\tilde{Z}_{rijk}|\mathcal{X}_{(-r)}, X_r]$, where $\mathcal{X}_{(-r)} = \{X_i, T_i, \Delta_i\}_{i \neq r}$. Now in order to prove (B.13) we will use a modification of Bernstein's inequality (see Theorem 1.2A in [29]). Using the notation $\tilde{\mathcal{X}}_{r-1,ijkl} = \{\tilde{X}_{1,ijkl}, \dots, \tilde{X}_{r-1,ijkl}\}$, if the following is satisfied :

$$E[\tilde{X}_{rijkl}|\tilde{\mathcal{X}}_{r-1,ijkl}] = 0, \quad (\text{B.18})$$

$$\sum_{r=1}^n E[\tilde{X}_{rijkl}^2|\tilde{\mathcal{X}}_{r-1,ijkl}] \leq v_n, \quad (\text{B.19})$$

and

$$E[\tilde{X}_{rijkl}^p|\tilde{\mathcal{X}}_{r-1,ijkl}] \leq \frac{1}{2} E[\tilde{X}_{rijkl}^2|\tilde{\mathcal{X}}_{r-1,ijkl}] L_n^{p-2} p!, \quad (\text{B.20})$$

where $L_n > 0$ and $v_n > 0$ are constants, we have

$$P\left(\sum_{r=1}^n \tilde{X}_{rijkl} > \lambda_n\right) \leq \exp\left\{-\lambda_n^2/2[v_n + L_n \lambda_n]\right\}.$$

We will use now, and show later that the conditions (B.18), (B.19) and (B.20) can be verified for constants $v_n = C a_n (nh_n)^{-1} (\log n)^\alpha$ and $L_n = C (nh_n)^{-1} (\log n)^\alpha$. Now, for $\lambda_n = c_1 a_n^{1/2} (nh_n)^{-1/2} (\log n)^{1/2+\alpha}$, where c_1 is a positive constant to be specified further on, we have

$$P(\{A_n > 2\lambda_n\} \cap D_n) \leq P\left(\max_{l=1, \dots, k_n} \max_{1 \leq i \leq m_n-1} \max_{-b_n \leq j, k \leq b_n} \left| \sum_{r=1}^n X_{rijkl} \right| > 2\lambda_n\right) \\ \leq P\left(\max_{l=1, \dots, k_n} \max_{1 \leq i \leq m_n-1} \max_{-b_n \leq j, k \leq b_n} \left| \sum_{r=1}^n \tilde{X}_{rijkl} \right| > \lambda_n\right) \\ \leq 2k_n(m_n-1)(2b_n+1)^2 \exp\left\{-C \lambda_n^2 / \left(\frac{a_n (\log n)^\alpha}{nh_n} + \frac{\lambda_n (\log n)^\alpha}{nh_n}\right)\right\} \\ \leq 2k_n(m_n-1)(2b_n+1)^2 n^{-c_1 C},$$

for some constant $C > 0$. For the second inequality we used that $\lambda_n > \sum_{r=1}^n E[\tilde{Z}_{rijk}|\mathcal{X}_{(-r)}, X_r]$ by (B.23) below, while for the third inequality we used the modified Bernstein's inequality. Since, by proper choice of c_1 , this can be made summable, using the Borel-Cantelli lemma we get $P(\cap_{m=1}^{\infty} \cup_{n=m}^{\infty} \{\{A_n > 2\lambda_n\} \cap D_n\}) = 0$. From here we can calculate

$$P\left(\bigcap_{m=1}^{\infty} \bigcup_{n=m}^{\infty} \{A_n > 2\lambda_n\}\right) \leq P\left(\bigcap_{m=1}^{\infty} \bigcup_{n=m}^{\infty} \left[\{\{A_n > 2\lambda_n\} \cap D_n\} \cup D_n^C\right]\right) \\ \leq P\left(\bigcap_{m=1}^{\infty} \bigcup_{n=m}^{\infty} \{\{A_n > 2\lambda_n\} \cap D_n\}\right) + P\left(\bigcap_{m=1}^{\infty} \bigcup_{n=m}^{\infty} D_n^C\right).$$

As we have just shown, the first term on the right hand side is 0 by the Borel-Cantelli lemma, while the second term is 0, since $P(\cup_{m=1}^{\infty} \cap_{n=m}^{\infty} D_n) = 1$. Therefore, this proves (B.13) and subsequently (B.11). Finally, to show the conditions that allowed us to use the modified Bernstein's inequality, we start with condition (B.18), that is satisfied since by definition $E[\tilde{X}_{ri jkl}|\mathcal{X}_{(-r)}, X_r] = 0$. Condition (B.20) follows from

$$\begin{aligned} E[\tilde{X}_{ri jkl}^p|\mathcal{X}_{r-1,ijkl}] &\leq E[\tilde{X}_{ri jkl}^2 \tilde{W}_{nr}^{p-2}(x_l, h_n)|\mathcal{X}_{r-1,ijkl}] \\ &\leq E[\tilde{X}_{ri jkl}^2|\mathcal{X}_{r-1,ijkl}](C'(nh_n)^{-1}(\log n)^\alpha)^{(p-2)}, \end{aligned}$$

where the last inequality is uniform in r, i, j, k and l . Before continuing we calculate:

$$\begin{aligned} E[\tilde{X}_{ri jkl}^2|\mathcal{X}_{(-r)}, X_r] &= \tilde{W}_{nr}^2(x_l, h_n) \left\{ \left| H_e(y_{ik} + \tilde{\Delta}_{(-r)}(y_{ik}, X_r)|X_r) - H_e(y_{ij} + \tilde{\Delta}_{(-r)}(y_{ij}, X_r)|X_r) \right| \right. \\ &\quad - \left[H_e(y_{ik} + \tilde{\Delta}_{(-r)}(y_{ik}, X_r)|X_r) - H_e(y_{ij} + \tilde{\Delta}_{(-r)}(y_{ij}, X_r)|X_r) \right]^2 \\ &\quad + E \left[\{\tilde{Z}_{ri jk} - E[\tilde{Z}_{ri jk}|\mathcal{X}_{(-r)}, X_r]\}^2|\mathcal{X}_{(-r)}, X_r \right] \Big\} \\ &= \tilde{W}_{nr}^2(x_l, h_n) [a_n + R_n], \end{aligned} \tag{B.21}$$

where $|R_n| \leq C(a_n^2(\log n)^{2\alpha} + (nh_n)^{-1}(\log n)^\alpha)$ uniformly in r, i, j, k and l . To bound the first and the second difference above we use the following calculation:

$$\begin{aligned} &H_e(y_{ik} + \tilde{\Delta}_{(-r)}(y_{ik}, X_r)|X_r) - H_e(y_{ij} + \tilde{\Delta}_{(-r)}(y_{ij}, X_r)|X_r) \\ &= [H_e(y_{ik}|X_r) - H_e(y_{ij}|X_r)] \\ &\quad + [H'_e(y_{ik}|x)\tilde{\Delta}_{(-r)}(y_{ik}, X_r) - H'_e(y_{ij}|x)\tilde{\Delta}_{(-r)}(y_{ij}, X_r)] \\ &\quad + \left[\frac{1}{2}H''_e(\xi_{ik}|x)\tilde{\Delta}_{(-r)}^2(y_{ik}, X_r) - \frac{1}{2}H''_e(\xi_{ij}|x)\tilde{\Delta}_{(-r)}^2(y_{ij}, X_r) \right] \\ &= O(a_n) + R'_n, \end{aligned} \tag{B.22}$$

uniformly in r, i, j and k , where $|R'_n| \leq C(a_n^2(\log n)^\alpha + a_n^2(\log n)^{2\alpha})$ and ξ_{it} is between y_{it} and $y_{it} + \tilde{\Delta}_{(-r)}(y_{it}, X_r)$, $t = k, j$. For the second and the third term of (B.22) we used (B.16) and assumptions (A5)(ii) and (A5)(iii). To bound the third term in (B.21) we use the following reasoning. We first define $c_n = C'(nh_n)^{-1}(\log n)^\alpha$. Now, on the set D_n we can conclude that the variable $I(E_r \leq s + \Delta(s, X_r))$ lies in between $I(E_r \leq s + \Delta_{(-r)}(s, X_r) - sc_n - c_n)$ and $I(E_r \leq s + \Delta_{(-r)}(s, X_r) + sc_n + c_n)$. Therefore, we have that

$$\begin{aligned} |E[Z_r(s)I_{D_n}|\mathcal{X}_{(-r)}, X_r]| &\leq E \left[I(E_r \leq s + \tilde{\Delta}_{(-r)}(s, X_r) + sc_n + c_n) \right. \\ &\quad \left. - I(E_r \leq s + \tilde{\Delta}_{(-r)}(s, X_r) - sc_n - c_n) \right] |\mathcal{X}_{(-r)}, X_r| \\ &\leq H_e(s + \tilde{\Delta}_{(-r)}(s, X_r) + sc_n + c_n|X_r) \\ &\quad - H_e(s + \tilde{\Delta}_{(-r)}(s, X_r) - sc_n - c_n|X_r) \\ &\leq 2 \sup_{s, x} |H'_e(s|x)|[sc_n + c_n] \\ &\leq C(nh_n)^{-1}(\log n)^\alpha, \end{aligned} \tag{B.23}$$

for some constant $C > 0$, uniformly in $-\infty < s < \infty$ and for all $r \leq n$. The last inequality follows from assumption (A5)(ii). This proves (B.21). Condition (B.19) is now satisfied, since $\sum_{r=1}^n E[\tilde{X}_{ri jkl}^2|\mathcal{X}_{r-1,ijkl}] \leq Ca_n(nh_n)^{-1}(\log n)^\alpha$ uniformly, because of (B.21). This completes the proof. $\square$
