Mears

Background

Algorithm

Optimisations

Results

1 Background

2 Algorithm

3 Optimisations

4 Results

- SAT theory: conjunction of clauses
 - e.g. $T = (a \vee b \vee c) \wedge (d \vee e) \wedge \dots$
 - (or $T = \{a, b, c\} \wedge \{d, e\} \wedge \dots$)
- Assignment α : set of literals currently true
 - e.g. $\alpha = \{a, \neg b, \neg e, d, g\}$
- Decision literals $\delta \subseteq \alpha$: choices made by search
 - e.g. $\delta = \{a, \neg e\}$
- Explanations: why is $\ell \in \alpha$?
 - $\text{expl}(\ell) = \text{clause}$
 - e.g. $\text{expl}(d) = \{d, e\}$
 - Only for propagated literals (those in $\alpha \setminus \delta$)

Symmetries

- A **symmetry** of T is a permutation on the literals of $T \dots$
 - e.g. $\sigma = (ab\neg c)(de)$
- \dots that satisfies these conditions:
 - $\sigma(\alpha)$ is a model of $T \Leftrightarrow \alpha$ is a model of T
 - $\sigma(\neg \ell) = \neg \sigma(\ell)$
- Symmetries lift naturally to clauses and theories.

Denecker,
Christopher
Mears

Background

Algorithm

Optimisations

Results

- If S is the symmetry group of theory T , and T entails the clause $\alpha \rightarrow \ell$, then T also entails the clause $\sigma(\alpha) \rightarrow \sigma(\ell)$.
- There are many such $\sigma(\alpha) \rightarrow \sigma(\ell)$ clauses (too many!)
- We use a **weak activity** heuristic to detect useful $\sigma(\alpha) \rightarrow \sigma(\ell)$ clauses: ones that propagate.

Activity

Symmetry Propagation

Jo Devriendt,
Bart Bogaerts,
Broes De Cat,
Marc
Denecker,
Christopher
Mears

Background

Algorithm

Optimisations

Results

- Symmetry σ is **active** under α if:
 - $\sigma(\alpha) = \alpha$
- During search:
 - α is the set of true literals,
 - $\delta \subseteq \alpha$ is the set of search decisions.
- Symmetry σ is **weakly active** for δ under α if:
 - $\sigma(\delta) \subseteq \alpha$
- **Asymmetric** literal: literal $l \in \alpha$ where $\sigma(l) \notin \alpha$
 - (σ is not active, but might be weakly active)

Overview

Symmetry Propagation

Jo Devriendt,
Bart Bogaerts,
Broes De Cat,
Marc
Denecker,
Christopher
Mears

Background

Algorithm

Optimisations

Results

```
repeat
  while there is a unit clause do
    run unit propagation
  end while
  for each weakly active symmetry  $\sigma$  in  $S$  do
    if there is an asymmetric literal  $\ell$  for  $\sigma$  then
      add  $\sigma(\ell)$  to  $\alpha$ 
      define  $\text{expl}(\sigma(\ell)) = \sigma(\text{expl}(\ell))$ 
      add  $\text{expl}(\sigma(\ell))$  to  $T$ 
      break and go back to unit propagation
    end if
  end for
until conflict, or no new literals propagated
```

Example

Symmetry Propagation

Jo Devriendt,
Bart Bogaerts,
Broes De Cat,
Marc
Denecker,
Christopher
Mears

$$T = \{\neg f, a\} \wedge \{\neg f, b\} \wedge \{\neg a, d\} \wedge \{\neg b, e, c\} \wedge \{\neg c, \neg g\}, \{\neg c, g\}$$

$$S = \{\sigma\} = \{(ab)(de)\}$$

$$\alpha = \emptyset$$

$$\delta = \emptyset$$

Background

Algorithm

Optimisations

Results

Example

Symmetry Propagation

Jo Devriendt,
Bart Bogaerts,
Broes De Cat,
Marc
Denecker,
Christopher
Mears

Background

Algorithm

Optimisations

Results

$$T = \{\neg f, a\} \wedge \{\neg f, b\} \wedge \{\neg a, d\} \wedge \{\neg b, e, c\} \wedge \{\neg c, \neg g\}, \{\neg c, g\}$$

$$S = \{\sigma\} = \{(ab)(de)\}$$

$$\alpha = \{\mathbf{a}\}$$

$$\delta = \{\mathbf{a}\}$$

- Search chooses a

Example

Symmetry Propagation

Jo Devriendt,
Bart Bogaerts,
Broes De Cat,
Marc
Denecker,
Christopher
Mears

Background

Algorithm

Optimisations

Results

$$T = \{\neg f, a\} \wedge \{\neg f, b\} \wedge \{\neg a, d\} \wedge \{\neg b, e, c\} \wedge \{\neg c, \neg g\}, \{\neg c, g\}$$

$$S = \{\sigma\} = \{(ab)(de)\}$$

$$\alpha = \{a, \mathbf{d}\}$$

$$\delta = \{a\}$$

- Unit propagation infers d
- σ is not weakly active (because $\sigma(\delta) \not\subseteq \alpha$)
- a is first asymmetric literal for σ (because $\sigma(a) \notin \alpha$)

Example

Symmetry Propagation

Jo Devriendt,
Bart Bogaerts,
Broes De Cat,
Marc
Denecker,
Christopher
Mears

Background

Algorithm

Optimisations

Results

$$T = \{\neg f, a\} \wedge \{\neg f, b\} \wedge \{\neg a, d\} \wedge \{\neg b, e, c\} \wedge \{\neg c, \neg g\}, \{\neg c, g\}$$

$$S = \{\sigma\} = \{(ab)(de)\}$$

$$\alpha = \{a, d, \mathbf{f}\}$$

$$\delta = \{a, \mathbf{f}\}$$

- Search chooses f

Example

Symmetry Propagation

Jo Devriendt,
Bart Bogaerts,
Broes De Cat,
Marc
Denecker,
Christopher
Mears

Background

Algorithm

Optimisations

Results

$$T = \{\neg f, a\} \wedge \{\neg f, b\} \wedge \{\neg a, d\} \wedge \{\neg b, e, c\} \wedge \{\neg c, \neg g\}, \{\neg c, g\}$$

$$S = \{\sigma\} = \{(ab)(de)\}$$

$$\alpha = \{a, d, f, \mathbf{b}\}$$

$$\delta = \{a, f\}$$

- Unit propagation infers b

Example

Symmetry Propagation

Jo Devriendt,
Bart Bogaerts,
Broes De Cat,
Marc
Denecker,
Christopher
Mears

Background

Algorithm

Optimisations

Results

$$T = \{\neg f, a\} \wedge \{\neg f, b\} \wedge \{\neg a, d\} \wedge \{\neg b, e, c\} \wedge \{\neg c, \neg g\}, \{\neg c, g\}$$

$$S = \{\sigma\} = \{(ab)(de)\}$$

$$\alpha = \{a, d, f, b\}$$

$$\delta = \{a, f\}$$

- σ is now weakly active (but not active)
- First asymmetric literal for σ is now d

Example

Symmetry Propagation

Jo Devriendt,
Bart Bogaerts,
Broes De Cat,
Marc
Denecker,
Christopher
Mears

Background

Algorithm

Optimisations

Results

$$T = \{\neg f, a\} \wedge \{\neg f, b\} \wedge \{\neg a, d\} \wedge \{\neg b, e, c\} \wedge \{\neg c, \neg g\}, \{\neg c, g\}$$

$$S = \{\sigma\} = \{(ab)(de)\}$$

$$\alpha = \{a, d, f, b, e\}$$

$$\delta = \{a, f\}$$

- σ is now weakly active (but not active)
- First asymmetric literal for σ is now d
- Symmetric propagation infers $\sigma(d)$, which is e
- $\text{expl}(e) = \sigma(\text{expl}(d)) = \{\neg b, e\}$

Example

Symmetry Propagation

Jo Devriendt,
Bart Bogaerts,
Broes De Cat,
Marc
Denecker,
Christopher
Mears

Background

Algorithm

Optimisations

Results

$$T = \{\neg f, a\} \wedge \{\neg f, b\} \wedge \{\neg a, d\} \wedge \{\neg b, e, c\} \wedge \{\neg c, \neg g\}, \{\neg c, g\}$$

$$S = \{\sigma\} = \{(ab)(de)\}$$

$$\alpha = \{a, d, f, b, e\}$$

$$\delta = \{a, f\}$$

- Unit propagation resumes (but nothing to do)
- σ is still weakly active
- No more asymmetric literals in α (σ is active)
- Search continues

Tracking weak activity

Symmetry Propagation

Jo Devriendt,
Bart Bogaerts,
Broes De Cat,
Marc
Denecker,
Christopher
Mears

Background

Algorithm

Optimisations

Results

- Symmetry σ is weakly active if $\sigma(\delta) \subseteq \alpha$.
- Each symmetry has a counter, initialised to zero.
- When a literal ℓ is added to α , for each symmetry σ :
 - if $\ell \in \delta$ and $\sigma(\ell) \notin \alpha$, increment counter
 - if $\sigma^{-1}(\ell) \in \delta$, decrement counter
- Symmetry is weakly active if counter is zero.
- Constant time per symmetry that involves ℓ .

Properties

- Symmetry propagation preserves completeness (never loops infinitely).
- Symmetry propagation preserves soundness, and does not choose solutions a priori.
- Choosing a choice literal can decrease or increase the set of weakly active symmetries.
- Propagating a literal only increases the set of weakly active symmetries.
- After propagation, all weakly active symmetries are active again
 - i.e. for all weakly active symmetries σ we have $\sigma(\alpha) = \alpha$

Optimisations

Results

Optimisation 1: Inverting Symmetries

Symmetry Propagation

Jo Devriendt,
Bart Bogaerts,
Broes De Cat,
Marc
Denecker,
Christopher
Mears

Background

Algorithm

Optimisations

Results

- An symmetry σ is *inverting* if $\sigma(\ell) = \neg\ell$ for some ℓ .
 - Such a literal ℓ is *inverting* for σ .
- When an inverting literal ℓ is propagated, symmetry propagation will cause $\sigma(\ell) = \neg\ell$ to be propagated, causing a conflict.
- When an inverting literal ℓ becomes a decision literal, then σ will become weakly inactive *permanently* (until backtracking undoes the choice of ℓ).
- Optimisation: make the search avoid choosing inverting literals as its decisions.

Optimisation 2: Inactive propagation

- Symmetry propagation is about finding implied unit clauses.
 - We find an explanation clause c such that weak activity guarantees $\sigma(c)$ is unit.
- In addition: generate clauses from existing explanations and weakly *inactive* symmetries and propagate with them if they are unit.

```
for each literal  $\ell \in \alpha \setminus \delta$  do  
  for each weakly inactive symmetry  $\sigma$  do  
    if  $\sigma(\text{expl}(\ell))$  is unit then  
      Propagate with it and resume unit propagation  
    end if  
  end for  
end for
```

Background

Algorithm

Optimisations

Results

- Compared Minisat, Minisat+Shatter, Minisat+SP, Minisat+SP+optimisations.
- Symmetric problems from SAT2011 competition and standard symmetric benchmarks.
- On satisfiable problems:
 - All methods work well.
 - Minisat+Shatter best.
- On unsatisfiable problems:
 - Symmetry breaking much more important.
 - Minisat+SP+optimisations best.

Results Examples

■ Satisfiable problem

Conclusions and Future Directions

- New approach to dynamic symmetry breaking
 - Better than existing methods on unsatisfiable instances
- Application to general constraint programming
- Search heuristics to maximise weakly active constraints
