**Can Participative Coach Behavior be Perceived as Controlling? The Role of Athletes’  
Expectations**

ACCEPTED MANUSCRIPT

26 **Abstract**

27 Coach-rated participative behavior has already been related to beneficial outcomes in athletes.  
28 Yet, research also indicates that allowing participation is not straightforward as it can  
29 sometimes be perceived as controlling or can even result in maladaptive outcomes. Building  
30 on implicit leadership theory, this study investigated the role of the alignment between coach-  
31 rated participation and athletes' expectations for participation in developing perceptions of  
32 domineering coach behavior in athletes, a specific type of controlling coach behavior. A  
33 secondary goal was to explore this relation in higher and lower level teams separately.  
34 Athletes' expectations for participative coach behavior, coach-rated participative behavior and  
35 athletes' perceptions of domineering coach behavior were measured in 61 team sport coaches  
36 and 654 athletes competing in football, volleyball, basketball, and handball competitions.  
37 Using polynomial regression with response surface analysis and controlling for athletes' sport  
38 experience, overall, results showed that a discrepancy between coach-rated participation and  
39 athletes' expectations for participation was related with increased perceptions of domineering  
40 coach behavior in athletes with more than 5 years of experience. However, in lower level  
41 teams, high amounts of participation seem optimal as only less coach-rated participation than  
42 expected predicted increased perceptions of domineering coach behavior in athletes with more  
43 than 15 years of experience. This in contrast with higher level teams where, independent of  
44 athletes' experience, both more and less coach-rated participation than expected were related  
45 with increased perceptions of domineering coach behavior in athletes. Current findings stress  
46 the need for a situation specific approach when offering participation to optimize its  
47 effectiveness.

48

### Highlights

- 49 - A discrepancy between coach-rated participation and athletes' expectations for  
50 participation was related with increased perceptions of domineering coach behavior in  
51 team sport athletes with more than 5 years of experience,  
52 - In higher level teams, both more and less participation than expected were related with  
53 increased perceptions of domineering coach behavior in athletes,  
54 - In lower level teams, only less participation than expected leads to increased perceptions  
55 of domineering coach behavior in athletes with more than 15 years of experience,  
56 - Coaches should try to get informed about the expectations of their athletes and inform  
57 their athletes about the reasons of their behavior to manage athletes' expectations.

### Keywords

60 Psychology, coaching, autonomy, team sport

## 61 Introduction

62 Sport coaches frequently adopt an autonomy-supportive coaching style to optimize  
63 athletes' motivation, motivational climate, and performance (5, 8, 24). A core aspect of this  
64 autonomy-supportive coaching style is involving athletes in decision-making processes and  
65 offering athletes meaningful choices. Recently these behaviors were classified as a  
66 participative approach, which is considered as a specific approach within the autonomy-  
67 supportive coaching style (7). Use of a participative approach has already been related to  
68 positive outcomes such as increased autonomous motivation, need satisfaction and  
69 involvement (1, 7).

70 However, despite frequently reported beneficial outcomes, some work demonstrated  
71 that providing participation is not always straightforward as participative behavior has been  
72 shown to be unrelated or even detrimental for autonomous motivation and performance-  
73 related outcomes in sport and educational settings (17, 22, 23). This might be explained by  
74 participation not necessarily feeding into autonomy satisfaction (23). For example, when  
75 people prefer others to make decisions for them, needing to choose by yourself will not result  
76 in experiencing a sense of volition, which reflects true autonomy (14). In this respect, not all  
77 contexts seem evenly suitable for participation. While individual sport settings are  
78 characterized by a one-on-one coach-athlete relationship, team sports are characterized by a  
79 complex coach-team-athlete relationship. Accordingly, team sport athletes will not only  
80 consider their own point of view when being offered choice but might also take the group  
81 norm into account. Research on conformism already stated that when choosers avert the  
82 existing group norm in their decision, they experience discomfort (30).

83 Furthermore, behavior that might be intended as participative by coaches is not always  
84 experienced accordingly by their athletes. Coaches tend to overestimate their amount of  
85 participative behavior as compared to their athletes' perceptions (7, 27). In addition, interest

86 in athletes' input and the provision of choice have even been related to increased perceptions  
87 of controlling coach behavior in athletes, thereby leading to increased anxiety (31). Yet,  
88 determinants that influence athletes' perceptions of coach-rated participative coach behavior  
89 are still underinvestigated in research on coaching and sport psychology.

### 90 **An Expectancy-Match Perspective on Participative Coach Behavior**

91 In business contexts, research grounded in implicit leadership theory (ILT: 10) already  
92 pointed towards the importance of followers' expectations when investigating followers'  
93 perceptions of leadership behavior and leader effectiveness (10). Based on ILT, followers  
94 create an implicit leadership scheme of their ideal leader (10, 11). This leadership scheme  
95 characterizes followers' expectations of the traits and abilities of an ideal leader and is based  
96 on socialization and past experiences with leaders. Building on ILT, Wong & Giessner (2018)  
97 recently showed that when leaders' empowerment behaviors are not aligned with followers'  
98 expectations for empowerment, followers evaluate these behaviors as laissez-faire.

99 While previous research in business contexts already pointed at the importance of  
100 followers' expectations, this perspective is currently lacking in research on coach behavior.  
101 Previous studies already showed that participative behavior might result in athletes perceiving  
102 their coach as controlling yet do not offer explanatory mechanisms for this relation (31). With  
103 controlling coach behavior being a multi-faceted concept, we will build upon an SDT-based  
104 circumplex model on coach behavior to define controlling coach behavior (7). Based on this  
105 model, we will focus on a domineering approach as a specific type of controlling coach  
106 behavior. A domineering approach encompasses coach behavior that involves the induction of  
107 guilt, personal attacks, and the exertion of power, which closely aligns with the reported  
108 maladaptive athletes' perceptions on participative coach behavior (17, 30, 31).

**109 Hypothesis development**

110           Following ILT, we propose that the previously reported controlling perceptions might  
111 be the result of unexpected amounts of participation, which in turn are misperceived as  
112 controlling behavior. As receiving choice is not always experienced as autonomy-supportive  
113 (23), choices can be subdivided into autonomy-supportive and controlling types (20).  
114 Autonomy-supportive types of choice offer choosers unrestricted options (e.g., no indication  
115 which option to choose) and support athletes' needs for autonomy by offering athletes the  
116 opportunity to adapt the environment towards their own preferences and experience a sense of  
117 volition (6). In contrast, controlling types of choices are marked by a sense of restriction or  
118 preference (e.g., subtle indications which option to choose). Thereby, controlling types of  
119 choice will primarily thwart athletes' needs for autonomy by inducing a feeling of obligation  
120 (6, 16).

121           We argue that athletes will perceive opportunities to choose as autonomy-supportive  
122 or controlling based on their expectations to choose. When coaches offer more participative  
123 behavior than expected, choosing might be perceived as an obligation rather than a true  
124 opportunity to express preferences because athletes must choose an option in a situation  
125 where they prefer not to choose (2). In this case, athletes will not perceive receiving actual  
126 autonomy as they will not experience a sense of volition. Furthermore, when athletes expect  
127 choice but are not provided the possibility to choose, athletes might also interpret this  
128 perceptual lack of choice as controlling coach behavior since their coach prevents them from  
129 expressing their own preferences (6).

**130 Present Study**

131           The present study will investigate the role of athletes' expectations in developing  
132 perceptions of domineering coach behavior among team sport coaches and athletes. As they  
133 function as active group members within a team, their behavior is inextricably influenced by

134 the team context (30). Consequently, as there is a high possibility for a discrepancy between  
135 coach-rated participative behavior and athletes' expectations for participation, since team  
136 athletes might have different or even conflicting expectations, team sports offer a valuable  
137 arena to test this hypothesis. We hypothesize that *a discrepancy between coach-rated*  
138 *participative behaviors and athletes' expectations for participation is related with increased*  
139 *perceptions of domineering coach behavior in athletes*. Given that implicit leadership  
140 schemes are constructed based on past experiences and socialization, implicit leadership  
141 schemes might become more rigid and important over time (10). That is, the more  
142 experienced athletes become, the more likely it might become that a deviation from their  
143 expectations leads to domineering coach perceptions. Therefore, we controlled for athletes'  
144 sport experience.

145 As a supplementary aim we performed exploratory analyses to investigate whether  
146 there are differences in expectations and responses between higher (international & national)  
147 and lower level (regional) sports. While the primary interest in higher level sports is on  
148 performance optimization, lower level sports primarily emphasize enjoyment (28). Previous  
149 research involving medal-winning athletes and coaches already showed that high-performance  
150 athletes stress the importance of the role of the coach as principal decision maker as this  
151 decision-making role might be crucial to maintain decision quality (19, 33). Consequently,  
152 athletes in higher level teams might expect lower amounts of participation while lower level  
153 teams primary benefit from a participative climate (7). As higher level team athletes expect  
154 their coaches to take more responsibilities and, in addition, coaches are being considered more  
155 crucial agents in determining team performance (32), we will also investigate whether a  
156 discrepancy between coach-rated participation and athletes' expectations for participation is  
157 equally related to perceptions of domineering coach behavior in higher and lower level teams.

158 The present study aims to contribute to the literature in various ways. Regarding the  
159 current inconsistent results on participative behavior, gaining insight in the role of athletes'  
160 expectations can clearly create an added value in literature on participative coach behavior by  
161 identifying boundary conditions for the effective use of participation. In addition, the study  
162 acted as a first step to test ILT in sport settings. This study also has practical implications.  
163 While athletes' perceptions of domineering coach behavior are negatively related to athletes'  
164 need-satisfaction and coach evaluations, athletes' perceptions of participative coach behavior  
165 are positively related to such outcomes (7). Providing coaches with specific boundary  
166 conditions for the usage of participation might reduce the risk that a well-intended  
167 participative approach can lead to maladaptive outcomes due to the induction of unwanted  
168 perceptions of domineering coach behavior in athletes.

## 169 **Materials & Methods**

### 170 **Participants**

171 A total of 61 coaches and 654 athletes participated in this study, with most coaches  
172 and athletes being male (coaches: 95.1%; athletes: 66.8%). From the 61 teams, a total of  
173 77.3% of the athletes participated in the research. Coaches were on average 42.11 ( $SD = 8.32$ )  
174 years old and had 11.38 ( $SD = 6.86$ ) years of experience in coaching. Athletes were on  
175 average 22.62 ( $SD = 5.08$ ) years old and had 14.46 ( $SD = 5.58$ ) years of experience in their  
176 sport. The sample consisted of volleyball (37.7%), football (34.4%), handball (14.8%) and  
177 basketball (13.1%) teams. Of the 61 teams, 29 teams competed at the highest or second  
178 highest division of their sport and were marked as higher level. 32 teams competed at lower  
179 national or regional competitions and were marked as lower level teams.

### 180 **Tools**

181 **Participative and domineering coach behavior.** Coach-rated participative behavior  
182 and athletes' domineering coach perceptions were measured using the Situations in Sports

183 Questionnaire (SIS-Q: 7). Spread over 15 vignette-based situations, 6 items ( $\alpha = .60$ ) rated the  
184 participative approach of the coach, and 5 items ( $\alpha = .64$ ) rated athletes' perceptions of  
185 domineering coach behavior. The internal consistency of the participative approach was in  
186 line with the original SIS-Q paper, while the domineering approach scored slightly lower.  
187 Coaches and athletes scaled each item based on the likelihood they/their coach would express  
188 the behavior in the specified vignette-based situation on a 7-point Likert scale ranging from 1  
189 (*does not describe me/my coach at all*) to 7 (*describes me/my coach extremely well*).

190 **Athletes' expectations for participation.** Athletes' expectations for participation  
191 were measured using a one-item survey ("I expect that my coach gives us (the team) the  
192 opportunity to provide input"). The item was measured using a 7-point Likert scale ranging  
193 from 1 (strongly disagree) to 7 (strongly agree).

#### 194 **Procedure**

195 Data collection was performed in [REDACTED]. Teams were contacted verbally  
196 or using e-mail when publicly available. The principal researchers contacted the coaches of  
197 the teams in collaboration with undergraduate movement science students from the host  
198 institution. Guidelines for standardized data collection were provided prior to the data  
199 collection. When the coaches agreed to participate in the research, athletes were contacted and  
200 fully informed of the research goals and methods. Each participant signed an active informed  
201 consent prior to the completion of the questionnaire and was free to participate and quit the  
202 research at any time. Due to COVID restrictions, data were collected using both pencil and  
203 paper and digital questionnaires. Participants were not rewarded for their participation. Hence,  
204 general conclusions of the research were shared with the participants at the end of the study.

#### 205 **Data analysis**

206 Comparisons of scores between coach and athlete perspectives or higher and lower  
207 level teams were conducted by means of independent samples T-tests for all variables of

208 interest. The main hypothesis was tested using Polynomial Regression with Response Surface  
209 Analysis (PNR-RSA). This technique has been frequently used in dyadic research concerning  
210 self-other ratings and showed to be superior to the calculation of Euclidean difference scores  
211 as this technique allows a more detailed interpretation of the surface area (see: 9, 13, 21, 25,  
212 26). To conduct the PNR-RSA, we followed the analytical steps from Nestler et al. (2019). As  
213 a first analytical step, participative coach behavior (X), athletes' expectations for participation  
214 (Y), athletes' perceptions of domineering coach behavior (Z) and athletes' experience (G)  
215 scores were centered around the scale midpoint, and three new variables were created:  $X^2$  and  
216  $Y^2$ , the squared value of the centered X and Y score, and XY, the product of the centered X  
217 and Y score. Final PNR RSA analysis were performed in R-Studio (Version 4.0.3 – Apple 64-  
218 bit) using the multilevel RSA statistical suite and PNR-RSA script from Nestler et al. (2019).  
219 Because athletes were nested within teams, a random intercept was added to the model. This  
220 enabled to estimate effects that are solely due to between-person differences (see: 32).  
221 Athletes' experience (G) was added to the regression model as a control variable. The script  
222 and regression model are available on Open Science Framework:

223 [https://osf.io/f68u9/?view\\_only=889bab77a50c4fcf89f74bced6be1a56](https://osf.io/f68u9/?view_only=889bab77a50c4fcf89f74bced6be1a56).

224 Final PNR RSA interpretation is based on five parameters, namely  $a_1$ ,  $a_2$ ,  $a_3$ ,  $a_4$  and  $a_5$ .  
225 Significance levels for each parameter were set at  $\alpha < 0,05$ . Parameter  $a_1$  and  $a_2$  indicated the  
226 shape of the graph above the line of congruence (LOC;  $X = Y$ ). A significant  $a_1$  indicates a  
227 descending ( $a_1 < 0$ ) or ascending ( $a_1 > 0$ ) course of the graph from the minimum value in  
228 agreement (-3, -3) to the maximum value in agreement (3, 3). Parameter  $a_2$  indicates the  
229 curvature of the graph above the line of congruence. A non-significant  $a_2$  indicates a linear  
230 shape of the graph above the line of congruence. A significant positive  $a_2$  indicates a convex  
231 curvature (U-shape), while a significant negative  $a_2$  indicates a concave curvature (inverted U-  
232 shape). We expected a non-significant  $a_1$  and  $a_2$  parameter. A visual representation is shown

233 in Figure 1. Parameter  $a_3$  and  $a_4$  indicate the shape of the graph above the line of incongruence  
234 (LOIC;  $X = -Y$ ). A significant  $a_3$  indicates a descending ( $a_3 < 0$ ) or ascending ( $a_3 > 0$ ) course  
235 of the graph from incongruence value (3, -3) to (-3, 3). Parameter  $a_4$  indicates the curvature of  
236 the graph above the line of incongruence. A non-significant  $a_4$  indicates a linear shape of the  
237 graph above the line of incongruence. A significant positive  $a_4$  indicates a convex curvature  
238 (U-shape), while a significant negative  $a_4$  indicates a concave curvature (inverted U-shape).  
239 We expected a non-significant  $a_3$  and significant positive  $a_4$  parameter. A visual  
240 representation can be found in Figure 1. Finally, parameter  $a_5$  compares the positioning of the  
241 first principal axis (FPA) with the line of congruence. When previous hypothesized conditions  
242 are met, a non-significant  $a_5$  indicates an alignment of the FPA and LOC. When  $a_5$  is  
243 significant this indicates a difference in position or course between the FPA and the LOC. We  
244 expected a non-significant  $a_5$  parameter. The model controlled for athletes' experience and  
245 calculated the regions of positive significance, negative significance, and non-significance for  
246 each a-parameter.

## 247 **Results**

### 248 **Descriptives**

249 Means, standard deviations, internal consistencies and intercorrelations between the  
250 main study variables are listed in Table 1. Based on the independent samples T-tests, athletes  
251 had significant higher expectations for participation than coach-rated participation ( $t(653) =$   
252  $16.285, p < 0.001$ ). In addition, athletes' perceptions of participative behavior were lower than  
253 coach-rated participation ( $t(60) = -2.988, p < 0.01$ ). Comparing the scores of both higher ( $N =$   
254  $29$ ) and lower-level ( $N = 32$ ) teams, higher level athletes scored significantly lower on  
255 expectations for participation ( $t(652) = 2.051; p < 0.05$ ) and lower on participative perceptions  
256 ( $t(652) = 5.159; p < 0.001$ ). In contrast, coaches reported similar amounts of participative

257 behavior ( $t(59) = .771 ; p = 0.44$ ). Higher level athletes scored significantly higher on  
258 perceived domineering coach behavior ( $t(652) = -1,985; p < 0.05$ ).

### 259 **Participative Expectancy-match & Perceived Domineering Behavior**

260 Table 2 represents the significant regions of the a-parameters of the PNR RSA. Results  
261 for average experience are graphically presented in Figure 2a. Parameter  $a_1$  and  $a_2$  were not  
262 significant, indicating a constant linear shape of the graph above the LOC. Parameter  $a_3$  was  
263 not significant and parameter  $a_4$  was significant and positive for athletes with more than 5  
264 years of experience, indicating a convex shape of the graph above the LOIC with no  
265 difference between incongruence value (3, -3) and (-3, 3). Finally, parameter  $a_5$  was not  
266 significant, which indicated the FPA of the graph was in line with the LOC. These results  
267 partially confirmed the study's hypothesis as a discrepancy between athletes' expectations for  
268 participation and coach-rated participation was related with increased perceptions of  
269 domineering coach behavior for athletes with more than 5 years of experience.

### 270 **Higher- vs Lower-Level Polynomial Regression with Response Surface Analysis**

271 Table 2 represents the significant regions of the a-parameters of the PNR RSA. Results  
272 for average experience are graphically presented in Figure 2b and 2c. In higher level teams,  
273 PNR RSA parameter  $a_1$  and  $a_2$  were not significant, indicating a constant linear shape of the  
274 graph above the LOC. Parameter  $a_3$  was not significant and parameter  $a_4$  was significant and  
275 positive, indicating a convex shape of the graph above the LOIC with no difference between  
276 incongruence value (3, -3) and (-3, 3). Finally, Parameter  $a_5$  was not significant, which  
277 indicated that the FPA of the graph was in line with the LOC. These results are fully in line  
278 with the study's hypothesis.

279 No congruence effect was found for lower level athletes as parameter  $a_1$ ,  $a_2$  and  $a_4$   
280 were not significant. These results contradict our hypotheses. Hence, parameter  $a_3$  was  
281 significant and negative for athletes with more than 15 years of experience which indicated a

282 descending ( $a_3 < 0$ ) course of the graph from incongruence value (3, -3) to (-3, 3).  
283 Consequently, providing less participation than expected was related with elevated  
284 perceptions of domineering coach behavior for athletes with more than 15 years of  
285 experience.

## 286 Discussion

287 Our study confirmed that coach-rated participative behavior deviates from athlete-  
288 rated participative behavior (7, 27) and that the provision of choice, besides frequently  
289 reported beneficial outcomes, can also lead to perceptions of controlling coach behavior in  
290 athletes (31). Building on ILT, our study moved beyond these findings and revealed that a  
291 discrepancy between athletes' expectations for participation and coach-rated participation can  
292 be related with increased perceptions of domineering coach behavior in athletes. Gaining  
293 insight on such determinants is important as athletes' perceptions predict numerous outcomes  
294 such as athletes' well-being (4) and performance (12).

295 While our results were in congruence with the study's hypothesis in higher level  
296 teams, the hypothesis was rejected in lower level teams. Also, lower level athletes expected  
297 higher amounts of choice. This difference could possibly be explained by the fact that athletes  
298 in higher level teams, where performance is a primary goal, grant their coaches with decision  
299 power to guide them towards the desired performance (19). As complex decisions require  
300 detailed knowledge, athletes might also feel insufficiently competent to choose and therefore,  
301 expect their coach to make the decision. Having to choose when not expected might  
302 ultimately lead to feelings of obligation instead of experiencing a sense of volition for athletes  
303 in higher level teams. These findings correspond with other studies that have shown that  
304 receiving choice is not always experienced as autonomy-supportive (23). Also, when people  
305 deliberately choose for others to decide, this still can feed their sense of volition and lead to  
306 autonomy satisfaction as it is their own preference (14).

307 In lower level teams, athletes primarily emphasize enjoyment which requires sufficient  
308 autonomy-supportive coaching (7). This is also indicated by the higher average expected  
309 participation in lower level athletes. When athletes with extensive experience receive less  
310 choice than expected, they will experience their coach as controlling, which actively thwarts  
311 athletes' autonomy. This relation was not found among athletes with less experience which  
312 could be explained by ILT as implicit leadership schemes of less experienced athletes are still  
313 preliminary, while such schemes might become more rigid when athletes' experience  
314 increases. As opposed to the findings among higher level athletes, providing more  
315 participation than expected was unrelated to athletes' perceptions of domineering coach  
316 behavior. As the overall level of expected participation was relatively high among athletes in  
317 lower level teams, a potential ceiling-effect might have prevented coaches to provide more  
318 participation than expected. Given the absence of maladaptive perceptions when providing  
319 more participation than expected and considering the importance of autonomy-supportive  
320 coaching for motivational outcomes, high amounts of autonomy-supportive coaching can be  
321 recommended in lower level contexts. However, current results should be interpreted with  
322 caution as the explorative comparisons were conducted on limited sample sizes.

### 323 **Practical implications**

324 Our findings indicate that providing athletes with participative coach behavior is not  
325 straightforward in team sports. Where coaches primarily use a participative approach to  
326 involve athletes in the decision-making process, coaches should be aware of possible  
327 deflected perceptions and dangers of participation when their participative approach is not  
328 aligned with their athletes' expectations.

329 Based on current findings it seems important for coaches to gain insight in which  
330 situations athletes expect participation or not. This way, coaches can adapt their behavior  
331 towards these expectations. Yet, coaches will not always be capable to comply to athletes'

332 expectations due to group management reasons or athletes having conflicting or unrealistic  
333 expectations (e.g., 33, 34). For this reason, coaches should also try to manage athletes'  
334 expectations by providing a clear framework for their coaching approach. One potential  
335 strategy is therefore to proactively provide athletes with additional rationale for their approach  
336 and decisions, certainly when coaches cannot comply to their athletes' expectations. In this  
337 respect, previous research on choice already showed that additional rationale can reduce  
338 negative effects of option retaining (3, 29). In summary it currently seems important to  
339 facilitate an open dialogue culture where both coach and athlete actively contribute in a  
340 positive way. Coaches should therefore build a coach-athlete relation that stimulates  
341 proactivity and mutual information sharing. On the one hand, this helps coaches to get  
342 informed about the expectations of their athletes. On the other hand, athletes also get  
343 informed about the underlying reasons for their coaches' behavior, about the reasons why  
344 their coach might refrain from providing choice in particular situations (e.g., situations where  
345 coaches have more available knowledge or information or when decisions need to be made  
346 under time-pressure) or why they behave in a participative manner (e.g., situations where  
347 coaches want their athletes to learn to behave proactively).

#### 348 **Limitations & future research**

349 As with all research, this study comes with its limitations. First, our research was  
350 cross-sectional and thereby based on predictive relationships. Future research might benefit  
351 from longitudinal and experimental research designs to ensure direction and causality of the  
352 current findings. Second, the scale used to investigate coach behavior showed moderate  
353 reliabilities ( $\alpha = .60$  to  $.64$ ). Hence, these lower reliabilities are inherent to the SIS-Q as it  
354 disentangles coach behavior into different styles and approaches, but at the same time tries to  
355 capture a broad variety of behaviors within each style or approach which reduces alpha  
356 values. Still the current alpha value for the domineering approach was lower than the alpha

357 value within the study of Delrue et al. (2019). A potential explanation might reside within the  
358 sample composition as our sample only contained specific team sports, while the sample of  
359 Delrue et al. (2019) was based on data from both individual and team sports. This could  
360 indicate that the specific types of domineering behaviors (exert power, induce shame, or  
361 induce guilt) are less interrelated in the sport types within our study than in other sport types,  
362 although future work should further examine this assumption. Third, athletes' expectations for  
363 participation were measured using a one-item scale to reduce cognitive load. Future research  
364 could benefit from an adapted expectations scale where participative behavior and  
365 expectations for participation are matched item-wise instead of using a one-item scale (35).

366 Future research should also investigate the importance of athletes' expectations in  
367 individual sports. In addition, future research should focus on other behaviors and outcomes.  
368 For example, Lambert et al. (2012) already showed that unexpected amounts of structure, for  
369 example clarifying task responsibilities or providing direction, are related with unfavorable  
370 outcomes in business settings. Finally, as coaches will not always be capable to meet athletes'  
371 expectations, research is needed on how coaches can manage athletes' expectations as this can  
372 facilitate the alignment between coach-rated participative behavior and expected participative  
373 behavior.

#### 374 **Conclusions**

375 Building on ILT, the current study showed that when participative coach behaviors are  
376 not aligned with athletes' expectations for participation, they are related to increased  
377 perceptions of domineering coach behavior in team sport athletes with more than 5 years of  
378 experience. However, exploratory findings showed that a discrepancy between coach-rated  
379 participation and athletes' expectations for participation is related with increased perceptions  
380 of domineering coach behavior in all higher-level team sport athletes, while only less  
381 participation than expected is related with elevated domineering perceptions in lower level

382 athletes with more than 15 years of experience. Future research is needed to validate our  
383 findings within a broader range of sport types and investigate the importance of athletes'  
384 expectations for other coaching approaches.
